There are two evident inconsistencies here: (1) considering the changes in the glomerular loops in nephritis equivalent to the arteriole changes in sclerosis, and (2) assuming that hypertension does not result till all the glomerular loops are involved in nephritis, while it occurs when only part of the arterioles are diseased in sclerosis. It is also weak, it seems to me, to regard a single structure, the glomerulus, as the pivot of renal inflammation, instead of viewing the changes in all the kidney structures more in proportion.

In my opinion Delafield's comprehension of the whole subject is broader, his understanding of congestion, of degeneration, and of acute inflammation clearer and better defined. Chronic nephritis, however, was too difficult for him to solve without the aid of the recent knowledge of renal function. It is to this problem, especially, that Volhard and Fahr address themselves, dividing Delafield's chronic nephritis into nephrosis, nephritis, and sclerosis, and in support of their claims they make a most splendid and exhaustive study of renal function and all renal symptoms in the various subgroups.

The future only can determine just how much of their interpretation will be accorded the value of truth, but whatever the final verdict, their work is full of light and helpfulness to every student of kidney disease.

TEMPERATURE CONTROL AS RELATED TO IMPROVEMENT IN MILK, CREAM, AND BUTTER SUPPLIES, AND HOW IT SHOULD BE APPLIED.

BY J. M. W. KITCHEN, M.D., M.S.

EAST ORANGE, N. J.

PROBABLY every one who has even an ordinary comprehension of the relation of bacteria to the food of man, in reading the heading of the present thesis, would be likely to think that no one could point out anything new in connection with the influence of possible incubating temperatures on the quality of milk, cream and butter. Nevertheless, the simple fact is that the whole world is suffering greatly because of a lack of adequate practical application of information in regard to this subject. Millions of babies are suffering in health and even struggling for their lives today, because of a lack of perception of the specific knowledge of how dairy products should be treated and preserved after milk is drawn from the cow, and how such practice is largely connected with unrecognized or unpracticed principles. It seems incredible to have to conclude that not only does the scientific world not adequately understand the matter from a scientific point of view; but that the principles involved are not applied anywhere by any one in such manner as to secure desirable results. Yet this is a plain statement of the situation that should be recognized and remedied.

The "clean milk" movement has only inadequately effected its aim. Not two per cent. of the public milk supply is of the relatively clean character of "certified" milk; and none of that high cost product is free from the suspicion of being pathogenically infected, while it, as well as other grades, is more contaminated with putrefactive ferment products than should be the case with such relatively clean milk; and simply because temperature influence plus special methods are not applied in assuring unquestionably good character in certified milk. Tuberculous cows are frequently found in even the best guarded herds. Something has been accomplished through the education of producers, and in adopting methods of producing cleanly milk; but the truth still pertains, that *all* milk produced today becomes more or less infected at the time of its production; and usually largely infected, and that all milk and consequently all butter made are contaminated with decomposition and ferment products.

There is not a package of milk or cream or a pound of butter sold today that is as good as it should be, or as good as it can easily be made, because: (1) of the *uncertainty* that exists in regard to the character of all such products as to infections and toxic contaminations; (2) of the *certainty* that all such products are more or less contaminated with putrefactive products; and (3) none of these products is of the highest attainable gustatory excellence. Furthermore, none of these products is sold at as low a price as that for which they should be sold.

The reason for the existence of this state of affairs is, more than anything else, due to a lack of applying specifically, corrective and preventive

temperature influences practically continuously between the times of the drawing of the milk, and the consumption of the milk, or of the cream and butter derived from the milk. This defect is unquestionably due to ignorance as to the real existing condition, and as to how to meet and overcome that condition.

Incidentally, let me here first refer to one basic reason why such foods are not sold at lower prices. This is owing to the fact of the reprehensible activities of the several cattle breeding associations, breeders, experimental stations, the trade press, and dairy farmers, in unwarrantably holding the idea that an unreasonably large amount of milk production in the cow is a virtue. The world does not need more milk; it needs a lesser amount of milk, but milk of better quality. Galactorrhoea in the cow is a disease, as well as in the human female, that results in a decrease of constitutional strength, depleted breeding ability, increased tendency to mammary and other troubles, and sensitivity to the invasion of bovine tuberculosis, and other troubles. To counteract even partly such tendencies in high power cows, they must be met by an increased uneconomic feeding of easily digested, high priced grain concentrates and other foods, if the tendencies are to be counteracted and constitutional strength maintained in the cow.

It is nonsensical to urge as a hygienic measure, a large consumption of fluid milk by adults, whose digestive apparatus should be strengthened in digesting solid foods. Public economies, as well as hygiene, call for a larger direct consumption of grains by man, that are now fed to high power cows to maintain constitutional strength, and increase milk flow in cows. A greater proportion of the milk supply should be produced from cheap, coarse, by-product farm fodders consumed by a larger number of cows. If one did not know there was so much ignorance in the world, there would almost seem to be a criminal, concerted action on the part of those interested financially in keeping up this illusion. Those thus interested are making money, although the farmer-producer loses money and the public suffers in health and pocket. This is one of the causes that must be removed, if the public is to secure abundant supplies of milk and milk products at lowered prices.

The world at large is unaware of its ignorance in this connection, and it seemingly will require superhuman effort to dispel that ignorance. This is the more strange because of the fact that some physiological writers at least point out that the fermentative putrefactive charges that take place in foods containing albuminous principles are due to bacterial fermentations in such foods, and are effectuated through favorable incubating temperature influences. In fact, such writers state the range of temperatures at which the growth of putrefactive bacteria is possible. Yet the whole dairy industry, including producers, manufacturers, holders, and distributors, conduct their operations with an apparent more or less lack of cognizance of the existence of such scientific information; and the scientific world at large does not yet realize the resulting condition.

The outcome is that all of these food products are more or less contaminated with putrefactive

products and the products of putrefactive decompositions. Yet it is known that in the metabolic life history of all living cells, absorption and excretion occur; that all cellular excretory products, including lactic acid, are more or less noxious, and that some of such products are virulently toxic.

Some Health Boards even prevent the reuse of melted ice creams. The occurrence of serious disease, and even death, from fermentive products in various foods, is well known to all doctors of medicine. But a rational remedy for this situation is not applied anywhere today, to correct such existing conditions and to protect consumers from this menace. I have all the data and evidence needed to convince the minds of those whose scientific endorsement I want; but I am held up by a lack of scientific interest on the part of those whose endorsement would be of the speediest benefit to the whole world; and because I have not the physical ability personally to incite such interest, and to correct the preconceptions due to absorbed old general information and unsound conclusions of a personal nature that are usually held by those who have made a study of this tremendously large and complex subject. This writing is an appeal to the world, to open its mind to the attainment of something new in this connection that is of aggregate, immense importance.

After giving a dozen years of intensive study to this matter, I am more than ever astonished to find the commercial world is lacking in scientific information relating to such details, and is ignorant of the seemingly simple matter of how a remedy should be applied, and that even the most prominent authoritative research workers and instructors are lamentably ignorant of such matters. I have been personally in touch with a number of the most prominent scientists in the United States; and I have yet to find the first one who apparently knew all that he ought to know about this matter. Of course, there may be those having a higher grade of knowledge whom I have not met. A dozen years ago, I now know that I was then lamentably ignorant in this connection; but I did not know then that all of the world was so ignorant in this connection as it still is regarding a very few, simple propositions. I am herewith trying to present those propositions as simply and clearly as I can.

Infections of milk *always* occur at the time of the drawing of the milk, and usually are large. Seemingly, *Bacterium termo* and mould spores are omnipresent, and are ever acting in decomposing milk products. Even condensing and canning milk in which the milk is kept separate from atmospheric influence, does not seem to destroy infective matter and to prevent, in time, decomposition in the can. Of course, slight exposure to the atmosphere results in rapidly increased infections. Putrid volatile, diffusive, foul-smelling fumes are always being evolved in and around cows' stables. Some of this putrefactive matter is elaborated in the sebaceous glands of the hard hides of cows. The stench from a large number of cows congregated in "certified" milk producing plants, sensibly pollutes the atmosphere of a large area around such establishments. It is usually in considerable concentration in the stable atmosphere, and is inhaled by the cows. It impregnates the food in the stable, and is found

in the milk at the moment of its drawing from the cow by the milker's hands, which are always infected. Such volatile matters, which to say the least cannot be wholesome, may be eliminated through simple temperature influences; but the general practice is to cool the milk before this putrid matter is sufficiently eliminated from the milk. In the cooling of the milk, atmospheric infections occur, and the volatile putrefactive matters are more or less hidden by the cooling temperature, but are retained in the milk.

The bacterial infections from the milker's hands, the hairs of the cow, the dust in the barn, etc., are usually all more or less allowed to proliferate in the milk *before* the milk is pasteurized, and this proliferation is due to a lack of temperature control. This proliferation evolves more or less metabolic excretions during such growth, and before the bulk of bacteria in the milk are destroyed by heat. It should be noted that there is always an undestroyed residue that resists pasteurizing heat, and it seems that this undestroyed residue may be of a vicious type. What occurs when the large proportion of bacteria that have undergone proliferation is destroyed by pasteurizing heat? If the conclusions of Vaughan and his students of the Michigan University and others are acceptable, the destruction of bacteria in milk liberates protein split poisons.

I believe that the bad effects presumably produced by pasteurization are due to inherent bad qualities in the milk prior to its heating, and to disruption of the proliferated bacteria in the milk; and that if good milk is heated moderately, no bad effects of the heating will be observed; though I theoretically believe that the less milk is heated, the better; still because of the danger of pathogenic infections, all milk should be heated. I am told by pediatricists, who have been compelled to use dried milk because good fluid milk was unavailable, that they do not see scurvy following dried milk feeding, and notwithstanding that orange juice is omitted. Now all dried milk has been subjected to a very high temperature influence, but has had its volatile constituents driven off in the heating process. It all depends upon the nature of the temperature influence when applied, whether such influences are beneficial or otherwise.

In general practice, the undestroyed residues of bacteria and spores in milk are allowed to grow, because of the temperature at which milk is generally held during its distribution; and this is merely due to lack of temperature control. What occurs when milk gets into the hands of consumers, we all know; but I imagine that very few fully understand the nature of the changes in the milk, and the results on health, from a purely sanitary point of view. Many would disclaim that assertion; but back of it is the fact that those who should know all about such changes in milk are relatively ignorant as to many points.

Is it any wonder that even the most accomplished of our pediatricists have so little "luck" in feeding bottle fed babies? The truth is that they cannot get cows' milk of basically entirely good character to use in their prescriptions and modifications. If the babies of this day are not still being fed poisons in their cows' milk feeding, my powers of deduction and observation are senile, or undeveloped.

Briefly outlined, the evidence that is conclusive to my mind is: the symptoms exhibited by bottle fed babies that have died by the millions, and are still dying in lesser numbers, are homologous with the symptoms produced by other poisons; that the toxins directly produced in the body by pathogenic bacteria require a stage of incubation after infection; that the symptoms are more or less like those of intestinal autointoxication, and of ferment-producing blood irritants of dietary origin; that in artificial feeding, milk that is subjected to such heating influences as will drive off the volatile, putrefactive products has a lesser malign influence; that babies do better in cold weather when there is a lessened fermentation in market milk; that the experience of a hundred or more years shows even the fatal influences of putrefactive products; that botulism and other putrefactive conditions in cheese and other substances have deadly effects; that the latest findings as to the lethal power of protein split poisons have been conclusively demonstrated; that the less milk is subjected to the influence of putrefactive fermentation, the better are its effects as a food; that periatrists have found by experience that even dried milk, in which the process of fermentation has been entirely stopped, and notwithstanding its obvious disadvantages, may act better than much of the public milk supplies; putrefactive volatile matters attach themselves very freely to organic tissues, and assumably, their absorption into the body is not followed quickly by their elimination from the body; all excretory principles exercise a depressive influence upon the vigor of bodily actions, either as pure depressants, or indirectly, through vagus irritations. Powerful toxins are produced in other foods through putrefactive, bacterial action. Even toxic ferments may be recovered, and if injected in the body, produce symptoms that are common to poisoning by many toxic agents. Immunization of the body against toxications due to bodily infection is largely dependent on the longevity of the producing bacteria; tuberculin in the cow's blood can be transferred to the milk, as well as other blood contaminants in the cow. There are probably non-volatile products formed in milk, and there is no evidence in hand showing that mere ordinary heating will destroy them. In fact, nothing but complete decomposition by heat, or the destruction by digestion, could be expected to remove such possible products. Hence, the need of preventing absolutely their formation. Infants are more sensitive to poisons than adults, who have become addicts; but even adults will show lethal symptoms from poisons produced by bacterial fermentations. Change from an infected and contaminated to a clean milk will produce beneficial results. Can any one in the light of such evidence, to which many other confirming data can be added, question the advisability of treating all milk in such a manner that all possible or real menacing character in it will be eliminated, and which is all practically possible through intelligently applied temperature influence?

What new practices then should be adopted? I think that some day in the distant future all milk will be preserved by holding it in insulated containers at temperatures sufficiently high to inhibit bacterial activity. In some warmer climates, milk

is heated twice a day to preserve it. But in the present undeveloped stage of public intelligence, it will be better to hold on to intensely cold temperatures in controlling ferment action in milk, as well as in butter. One of my latest evolved ideas is a solution of the troubles incident to lack of uniformity in the production of milk throughout the year. This is merely to condense milk surpluses during flush times, and coincidentally drive off volatile contaminants, deeply refrigerate and hold the milk until periods of shortage, and then reconstitute the milk by adding sterile water, and distributing the milk at a temperature only slightly above freezing. This simple idea would greatly improve the character of milk, cut down its cost to the consumer, and eliminate friction between producer and dealer.

There is no butter sold today that is not more or less teeming with living germs of uncertain character, though small quantities of good quality butter may be produced that are *relatively* free from living germs. Our National Bureau of Animal Industry reports that butter that the Bureau has bought on the open market, if injected into guinea pigs, results in their death from tuberculosis in three days. Butter made from pasteurized cream, that is infected to ferment for flavor after the pasteurization of the cream, is *not* pasteurized butter. Most of the butter sold is not even made from pasteurized cream. It may be that some "process" butters are free from live pathogenic and other germs, and have had volatile putrid matters eliminated; but in every case requiring "processing" to make it endurable to the human palate, there remains a suspicion that non-volatile products of putrefaction and of decomposed split proteins are present. There is no evidence in hand that such toxic matters are destroyed by the heat applied in processing butter, condensing milk, or drying milk. In fact, it is practically impossible to get rid of some of those products, and the processed butters have usually to be heavily salted to hide their presence. So far as I know, nothing is being done today to meet and overcome this butter situation.

All that needs to be done to relieve the situation, is to prevent all fermentations in milk through temperature influence, before it is pasteurized, drive off volatile contaminations by heat, pasteurize in a final container that has an efficient closure, and hold the milk in a non-fermentative temperature during its distribution. This presumes reasonable cleanliness in production. Strange as it may appear, this simple program is not carried out anywhere today. Very much the same plan should be effected in treating cream, and butter after it is made. Of course, there are numerous novel details to be applied in carrying out the principles involved, that may be desirable. The reason why such desirable practice is not carried out, is largely because scientists at the top have not perceived the need; the general idea being unwarrantably held that the milk publicly purveyed is good enough.

Probably this state of general ignorance and apparent lack of interest, is because few research workers have given sufficient time and study to collecting and estimating the value of the enormous amount of data and evidence that is attainable. I do not know of any one but myself who has done

the required, laborious work. Heineman, in his 700-page book, published in 1919, has accumulated almost all other knowledge, and gives it in his book, but he also states that there is still further information to be had in regard to this subject matter, open to research investigation. My beliefs in this matter came to me a dozen years ago, before I undertook the research work I did, which was initiated at the suggestion of the late Professor A. Jacobi, who had informed me several years ago that my conclusions as to toxic products in milk were in harmony with his clinical experience, which the medical world knows was vast and successful.

That the character of the public milk supplies is not good enough, is particularly evinced by the fact that so many pediatricists are prescribing dried milks for infant feeding, and in some cases, with apparently fairly good results. But I have a new little granddaughter who was nearly killed from feeding her a dried milk product that was prescribed by an unusually intelligent general medical attendant. A change of doctors was followed by the new-to-me prescription of a thickened gruel of farina and milk boiled for an hour, with an immediate beneficial effect. The trouble with dried milk is, that the milk is subjected to a very high heat in its dehydration, which through albuminous coagulation becomes more difficult of digestion, especially the larger particles that must pass undigested into the intestine and there set up irritation mechanically and from putrefactive fermentation. Furthermore, butter fat in dried *whole* milk quickly undergoes rancid decomposition, while a reasonable amount of butter in the food of infants is a harmless but concentrated source of constitutional force, and contains the mysterious growth principle of recent discovery. It is true that sugar may be sometimes used instead of fat as a force creator; but it is also true that germs do not thrive in pure butter fat that is not associated with protein principles of milk, and that sugar in the intestine is an excellent food for acid-forming germs, and may be difficult of disposal when absorbed into the blood.

All of the present existing troubles due to an inadequately abundant supply of milk of sufficient high character can be easily eliminated in the simplest manner through the influence of temperature intelligently applied; but I have not been able to transfer that seemingly elementary knowledge through literature alone, to the minds of most of the advanced students of the milk problem; probably because the minds of such individuals are so strongly and variously impressed with many preconceptions and personal conclusions that they have little or no interest in investigating new ideas in this connection. I have not yet solved the problem as to how I can personally get in touch with such individuals in a widely spread territory, especially in the United States, and to arrest and hold their attention long enough to displace their old impressions with those that are newer and of more value. A year or more ago, I asked a Humanitarian Foundation as a disinterested body to appoint and pay a commission of experts, to whom I could personally present my conclusions and supporting evidence, and explain the numerous details of the plan I have evolved, whose findings, when published, would be

generally accepted. So far my appeal has not been granted, on the ground that my plan includes the basic feature of making the money that is absolutely necessary to be expended in securing a preliminary public education, that would dominate the action of Health Boards, and of those engaged in the milk and butter trades. I hold that this was an unwarranted rejection on the part of a humanitarian agency working for the general good. There can be no advance practice in this connection that is not commercialized. The certified milk movement necessitated the investment of large amounts of capital, and because of those and other invested interests, further advance by the "certified" interests and on the part of other interests engaged in the milk and butter trades, is prevented.

In the meantime, if I stick to ineffective work, my seed-sowing may proliferate and influence in time this world of ours that is ignorant in so many matters. One confrère thinks that this matter should be left to an aroused conscience on the part of dealers. He does not say who is to arouse the conscience. Furthermore, individual selfishness is the outgrowth of the instinct of self-preservation that exists in all animal life. Milk dealers are not in business because of their health or for humanitarian purposes. They must be prodded up to do their duty through the action of health boards, or through the domination of self-protecting consumers, which in either case involves educating the public, with a preliminary interest and study on the part of scientists. Hence, these lines, which urge a general recognition of the fact that all of the present uncertainties, objectionable certainties, and menacing possibilities and probabilities, can be eliminated through intelligent application of temperature influences in a manner not now applied.

94 PROSPECT STREET.

MALFORMATIONS OF THE ANUS.

By CHARLES J. DRIECK, M.D.,

CHICAGO, ILL.

PROFESSOR OF RECTAL DISEASES, POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; RECTAL SURGEON TO PEOPLE'S HOSPITAL.

IMPERFORATE anus is one of those conditions that is only occasionally seen, but if complete it must be promptly and fully appreciated and quickly remedied or we lose the baby. The frequency of its occurrence varies with different statisticians. Moreau saw four cases in over forty years' experience in the maternity hospital at Paris; Couty in Havre saw three cases in 3,500 confinements, while Zohre in Vienna saw but two in 50,000 maternities (Tuttle).

The embryonic intestine is developed from the hypoplast and mesoblast. It consists of the foregut in the head fold, the midgut in the body, and the hindgut or rudimentary rectum which at first ends blindly. The hypoblast forms the mucous membrane while the mesoblast forms the muscular, peritoneal, and glandular structures. The blind end of the hindgut, the cloaca, receives through the allantois the secretions of both urinary and digestive tracts. Later the cloaca is divided into two parts, the anterior and larger part becoming the genital and urinary organs, the posterior portion being the enteron or rudimentary rectum which is still

closed. In normal development this separation is completed by the twelfth week of gestation. Imperfection of this septum causes many of the abnormalities of the rectum.

The anal canal forms about the fourth week by an involution of the epiblast which is called the proctodeum which compresses the outer and inner layers of the mesoblast until they are absorbed, and the hindgut and the proctodeum thus meet. The absorption of this septum fuses the rectum and anus. Sometimes this involution of the epiblast does not occur and there is no anus or it fails to connect with the rectum.

This fusion of the anal and rectal canals occurs on the anterior portion of the hindgut and thus leaves a cul-de-sac which is later absorbed, leaving the coccygeal gland or gland of Luschka, which remains in adult life. Imperfect absorption of the cul-de-sac leaves a congenital posterior rectoceles. It is also from this posterior cul-de-sac that dermoid cysts about the coccyx develop.

Many minor malformations of the anus go unobserved until later life, if found at all. The rectum and the anus are developed from different layers of the blastoderm and have different blood supplies. Arrest of development of one, therefore, is not necessarily associated with malformation of the other. Malformations of the anus (meaning the whole anal canal) are divided into:

1. Entire absence of the anus (failure of the proctodeum to invaginate).
2. Abnormal narrowing of the anus.
3. Occlusion of the anus: (a) Partial. (b) Complete.
4. Abnormal opening of the anus upon the skin.
5. Opening of the anus into vulva, perineum, or scrotum.

Entire Absence of the Anus.—Entire absence of all external evidence of the anus is very rare and is promptly noticed by the accoucher, but when the anus is imperfectly developed the defect may be easily overlooked. Sometimes only a few signs mark the location, as a depression or protrusion of the skin at this point, discoloration, or the peculiar puckering rugæ. Very rarely the raphe extends from the scrotum to the coccyx without a break. The presence or absence of skin markings of the anus, however, bear no relation to the point of termination of the rectum above. In fact, there is no way of determining beforehand which case can best be reached through the abdomen, and therefore all must be subjected to a careful perineal dissection. When the anus is occluded the rectum may terminate anywhere above the skin or open into some other viscus.

Very frequently we find associated with rectal malformations other abnormalities of the pelvis and genito-urinary organs, *i.e.* narrow pelvis, atrophy of the vagina, extrophy of the bladder, or hypospadias.

The *diagnosis* is simple at times and again very difficult. Where there is no trace of an anal opening the condition is at once recognized and, even if not, the failure to void meconium must attract attention by even the most careless nurse. The child soon becomes restless and constantly strains as if at stool. The abdomen distends and is tense, the skin is cyanosed, and in a couple of days the child

vomits its food and feces. In other words we have the picture of acute intestinal obstruction.

Abnormal Narrowing of the Anus.—Sometimes the anal canal is patent throughout and the anus may appear normal on the inspection, but the canal will be found constricted in some portion between the rectum and anal opening (a distance of one-half to one inch). This narrowing may be annular (diaphragm), a few fibers extending across the canal, or it may be lengthwise and extend the full last inch or more of the bowel. Such a malformation differs from the strictures of the rectum and anus that occur later in life, the result of inflammation or disease, in that there is no scar tissue. Connective tissue hypertrophy may be added later because of the trauma caused by the feces being driven through the narrow passage. Many individuals go through life with a partial occlusion of the anal canal and complain of chronic constipation, the real conditions being never discovered.

The *diagnosis* of the condition is much more difficult than the preceding, the total occlusion, because liquid feces and gas have exit and it is only later, when the feces are formed, that any disturbance is noted. The diagnosis is made by seeing the size of the fecal mass voided and by digital examination. Serremone, quoted by Tuttle, says that these people both in childhood and adult life are subject to anal fissures. It must, however, be remembered that fissures in infancy are frequently syphilitic.

Membranous Occlusion of the Anus.—This consists of a diaphragm across the anal canal. If at the outside of the anus, it will consist of the skin and appear as a continuation of the raphe. When above the anus, it is composed of mucous membrane or connective tissue. If the obstruction is only partial, it will appear as a crescentic band and the channel left may vary considerably in size. This partial occlusion is frequently met.

Complete obstruction is rare and of course demands immediate attention. When at the anus, the diaphragm resembles the hymen and is composed of fibrous or mucocutaneous tissue. It is thin and flexible. If the rectum is normal above, this membrane will bulge with meconium.

Opening of the Anus at Some Abnormal Point in the Perineum.—This is usually an abnormal opening of the rectum, although there is no other anus present. This abnormal orifice may be anywhere on the perineum, buttock, or to one side of the sacrum.

30 NORTH MICHIGAN AVENUE

A CONCEPT OF X-RAY PATHOLOGY.

X. DISLOCATIONS.

BY A. J. PACINI, M.D.,

WASHINGTON, D. C.

CHIEF OF X-RAY AND LABORATORY SECTION, HOSPITAL DIVISION,
U. S. PUBLIC HEALTH SERVICE.

DISLOCATIONS may be defined as the complete displacement of articular or other surfaces that comprise a joint. When the displacement is only partial, some of the joint surfaces still remain in normal apposition, the condition is called a subluxation. A dislocation may be open or closed; open, when the joint cavity is torn through and communicates with

the outside air. It is a closed dislocation when no outward communication occurs. Dislocations may be accompanied by pathological complications such as local injuries of the bones, vessels, nerves, viscera and soft parts. Symptoms and signs of dislocation are not separately distinctive, but are very closely interwoven. The x-ray is useful in distinguishing between dislocations and conditions which affect joints, more particularly the arthropathies. Tabes is an especial stumbling block.

Deformity in most dislocations is apparent and together with the patient's position is sometimes diagnostic; but the x-ray is necessary to establish either the presence or absence of concomitant fracture.

Dislocation of the Lower Jaw.—These form about two per cent. of the clinical observations though few are referred to the roentgenologist. They are practically unknown in infants and are extremely rare in the older ages. Luxation commonly is forward, though it may be backward or outward. The most common form is forward bilateral dislocation. It is generally accompanied by fracture of the mandible. Dislocations in directions other than forward, that is, backward, upward, inward and outward, are quite rare though readily recognized on the x-ray plate.

Dislocations of the Clavicle.—Either the sternal end of the clavicle may be dislocated forward, upward, inward or inward and backward; or the acromial end may show complete or incomplete dislocation which may be supra-acromial, subacromial or subcoracoid; or both ends of the clavicle may be dislocated at the same time.

In studying the sternoclavicular arthroidal articulation the x-rayist must be exceptionally careful of the posturing of the patient in order not to confuse the distorted projection of the sternal end of the clavicle onto or away from the sternalmanubrium. Presternal dislocations are the most common. The condition may be complete or merely a subluxation. When subluxed the bone is partly raised out of the sternoclavicular joint, the edge of its cartilage impinging against the sternum.

Upward dislocation is rare and is better detected by the x-ray than by the clinical examination.

Backward dislocations, especially backward and inward, are the rarest forms of inner-end dislocation. The condition is readily recognized by the x-ray and also by clinical methods. In three of eleven cases of backward dislocation emphysema was elicited by the x-ray, apparently incident to lung puncture and fracture of the ribs.

The acromioclavicular articulation is an arthroidal joint formed between the acromial extremity of the clavicle and the acromial process of the scapula. It is surrounded by the capsular ligament and is strengthened by the superior and inferior acromioclavicular ligaments and articular disks of cartilage and coracoclavicular ligament. The coracoclavicular ligament does not enter into the joint proper; but it is exceptionally important in acromial dislocations of the clavicle. The articulation slants and presents a flat surface, the clavicle lying on a level higher than the acromion. The normal separation in the acromioclavicular joint is equivalent to at least one centimeter. The joint may be completely or incompletely dislocated. When it is incomplete it is significant that the coracoclavicular ligament is intact

through the capsular ligament and perhaps the acromioclavicular ligament may be torn. When dislocation is complete the normal centimeter displacement is exaggerated. In x-raying the acromioclavicular joint to decide the presence or absence of dislocation it is exceptionally important that the joint be placed on the plate as nearly flat as anatomical conformation will allow, and that the central ray strikes the joint very nearly perpendicularly. If this is not done distortion may be produced and misinterpreted for dislocation.

Acromial end dislocations may be supra-acromial or upward, subacromial and subcoracoid. Of these, upward dislocation is the most common. For the x-ray detection of upward acromial end dislocation the patient is best posed in the upright position, both arms hanging freely at the sides. The exposure is made dorsoventrally. The plate is viewed with particular reference to the relative height of both clavicular acromial ends, usually there being great displacement upward on the side showing the dislocation. When the displacement is great the acromion will be overridden by the clavicle. Subacromial dislocation, though rare, is readily recognized by the downward and somewhat inward pointing of the acromial end of the clavicle. Subcoracoid dislocation is an extreme rarity and needs little comment.

Double dislocation of the clavicle and total dislocation appear to be confusing terms. It would seem that double dislocation should be used to describe that occurring in symmetrical joints only; while total dislocation might better be reserved for the simultaneous dislocation of both ends of the clavicle. Total dislocation is more readily detected than double dislocation by comparison of the injured with the uninjured side.

Shoulder Dislocations.—Shoulder dislocations may present four forms; anterior, posterior, downward and upward. Each form may be named in accordance with the degree of displacement as follows: (Speed)

1. Anterior dislocations.
 - (a) Subcoracoid complex—common form.
 - (b) Subcoracoid incomplete (*subluxation*).
 - (c) Intracoracoid.
 - (d) Subclavicular.
2. Posterior dislocations.
 - (a) Subacromial.
 - (b) Subspinous (scapular spine).
3. Downward dislocations.
 - (a) Subglenoid.
 - (b) Erecta.
4. Upward dislocations.

(a) Supraglenoid.	} Both very rare and accompanied by fracture.
(b) Supracoracoid.	

X-ray examination of the shoulder joint should be stereoscopic in order to eliminate the possibility of error in interpreting the type of dislocation. It is well, too, to ray the companion shoulder for comparison; although in this the roentgenologist must exercise utmost caution in obtaining as nearly identical posture of both shoulders as skill will permit in order to eliminate the exaggeration of anatomical displacement incident to the distortion of malposture.

Subcoracoid dislocation is the most common at the shoulder. It is unfortunate that the serious complications sometimes accompanying subcoracoid dislocation, including capsular tears, periosteal strip-

ping or splitting off of the glenoid cartilage can not at the time the injury is sustained be revealed with any precision by the x-ray. Detached tuberosities are readily apperceived. When the greater tuberosity is separated the bone formation may remain appearing in position owing to the attachment of periosteal shreds, or it may be greatly retracted and take the position high up behind the acromion. Blood vessels and nerves may be injured. The x-ray is useful in differentiating between cases of fracture of the anatomical and surgical neck of the humerus and dislocation. It is difficult clinically to diagnose a double condition of dislocation and fracture; and, unfortunately in some cases the x-ray is equally uncertain unless a most careful stereoscopic scrutiny is made.

Elbow Dislocation.—In studying the pathology of dislocations at the elbow it is essential to recall that the external condyle of the humerus articulates with the head of the radius by means of the capitellum and that the elbows of the trochlea, together with the aid of the lateral ligaments, guard and direct the movements between the ulna and the humerus. Clinically, the points of the external and internal condyle and olecranon assume practically a straight line with the arm in full extension; and in antero-posterior view of the fully extended arm its straight line can also be traced on the x-ray plate. If the swelling that may sometimes accompany a dislocation (or fracture) be so great as to impede the examination for the alignment of condylar and olecranon points, the x-ray may be used instead of palpation.

There are three general classes of elbow dislocation commonly met: those in which both bones (radius and ulna) are dislocated backward, laterally, forward, or divergent; dislocations in which the radius alone is misaligned; and, dislocations affecting only the ulna.

Backward dislocation of both ulna and radius is the frequent condition. The x-ray is immediately diagnostic and in addition may demonstrate certain complications, particularly fracture, that oftentimes accompany elbow luxation. When injury of the condyles accompanies backward dislocation of the elbow it is practically clinically impossible to make definitely certain of the complication; but the x-ray at once reveals the complicating fracture. The remaining types of both bone dislocation are readily recognized, though less frequently occurring.

Dislocation of the radius alone may be forward, backward or outward. Dislocations of the ulna are exceptionally uncommon and may be backward or forward. In the x-ray elicitation of these dislocations both elbows should be studied and if necessary stereoscopic examination should be made.

Dislocations of the Lower End of the Ulna.—Dislocations of the lower end of the ulna may be backward or forward. In comparison with the number of wrist injuries noted concomitant dislocation of the ulna is rare. It affects children more often than adults. The forward dislocations are even rarer than the backward. X-ray interest in these dislocations lies in detecting the possibility of an accompanying or complicating fracture.

Madelung's deformity, a progressive curvature of the radius, probably of rachitic origin, may be confused for a traumatic deformity of the wrist. It

is interesting to note that in Madelung's deformity the "law of multiple variations" is especially accentuated in regard to the carpi. The significance seems to lie in the fact that Madelung's deformity is associated with an imperfection of the joint cartilages and carpal development.

Carpal dislocations are readily observed. A convenient classification for dislocations of the hand and wrist is that which groups under (1) dislocations in the radial carpal joint; (2) dislocations in the intercarpal joint between the two rows of carpal bones; and (3) dislocations in the carpometacarpal joint.

Metacarpophalangeal dislocations of the fingers are readily recognized and require little review.

Dislocations of the Hip.—A discussion of Shenton's line has already been advanced. It is particularly in the question of hip dislocations that Shenton's line offers inestimable x-ray aid. Hip dislocations may be posterior or anterior and should be studied through the use of stereoscopic plates. In addition, there should also be used one large, plain plate in order to obtain a gross comparison of both hips.

Dislocations of the Patella.—These conditions are as interesting as they are rare. They may be classified as acute when they are divided with reference to the position of rest assumed by the patella, or chronic or recurrent when they may be redivided into congenital and other forms. Acute dislocation of the patella is generally accompanied by swelling sometimes due to hemorrhage from the capsule which fills the joint. The dislocation may be confused with fracture or other injuries to the knee joint; but the x-ray usually indicates the fundamental pathology. Dislocation of the knee remains an uncommon observation by reason of the unusual stability of the joint. The x-ray interest, aside from the rarity of the condition, rests with the possible injury to the vessels that pass through the popliteal space.

In a properly posed joint the popliteal space may be demonstrated with the suffusion of blood made plainly evident in addition to the anatomical separation of the tibia and femur.

The semilunar cartilages have elsewhere been discussed. The x-ray, contrary to general opinion, may furnish a very satisfactory aid. It is true that the cartilaginous disks rarely cause a distinct shadow in their normal condition; but in dislocations, owing to the continued unnatural irritation that is thrust on these bones, calcific infiltration is promoted and they may pass from radiopaque to radiolucent; so that with properly controlled technique it is sometimes possible definitely to indicate the abnormal position of these bones. In addition, the x-ray investigation may aid in differentiation by exposing other lesions of foreign bodies and fractures of tibial spine and other portions of the bones.

Ankle and Foot Dislocations.—True ankle dislocations are uncommon. There may be forward or backward, or inward and outward dislocation of the tibioastragalar joint. Dislocations of the great toe, when pronounced, are readily detected. In hallux valgus the position of the tarsal phalanges may be such as to suggest dislocation; so that in this condition the x-rayist must be careful not to express an erroneous opinion.

Medicolegal Notes.

County Board May Employ Physician to Examine Patients During Smallpox Epidemic, and Is Liable for His Fees.—In an action against a county in Nebraska on an alleged contract made between the county and the plaintiff, a physician, it appeared that the plaintiff was requested, at the instance of the board of health, to diagnose and examine the ailments of a number of persons, residents of the county, during a smallpox epidemic. There was evidence tending to show that the physician on the board of health was unable to diagnose the disease and called it "Cuban itch." No quarantine had been established, and many persons afflicted with the disease walked about the streets and in public, so that the epidemic got well under way before it was discovered what the ailment was. The plaintiff undertook the work, in this emergency, at the instance of the county board of health. Each of the specific examinations was made at the request of the board. There was evidence also that the chairman of the board of county commissioners requested that the county board of health take this action. The plaintiff made extended trips over the county, examining cases, so that quarantine might be established. When he made these examinations he also instructed the persons afflicted how to care for themselves and, in some cases, prescribed for them. These first trips were the only ones charged against the county. When his services were completed he filed a claim. The claim was disallowed by the board of county commissioners and he appealed to the district court, where the matter was tried without a jury and judgment was rendered in his favor for the full amount of the claim. But the county contended that the individuals receiving the services should be required to pay for them, and not the county, since these people, with one exception, were not paupers and not a county charge. The Nebraska Supreme Court, affirming the decision of the circuit court so far as concerned services rendered within the jurisdiction of the county board, found authority for holding the county liable in the Statute, sections 2737 and 2738, Rev. St. 1913. By these sections the county board is directed to make and enforce regulations to prevent the introduction and spread of contagious diseases within the county, and, to that end, to establish a county board of health, which is given jurisdiction over the matter throughout the county, except in incorporated cities and villages, where the local board fails to act with sufficient promptitude and efficiency in any emergency, it is expressly provided that the State board of health shall step in and enforce its own regulations in that county, and that the necessary expenses so incurred shall be borne by the county. It would seem to follow that when the county itself acts in an emergency it was not intended that it be limited in its powers more than the State board, and that the necessary expenses incurred should, in that event, also be chargeable to the county. Though it is not expressly provided that when the county acts in providing regulations to prevent the spread of disease the necessary expenses so incurred shall be a charge against the county, that liability must necessarily be inferred. If that were not true, then the county would, by law, be required to perform a duty and at the same time be prevented from using the means necessary to its performance. The county board could not quarantine without learning, through the services of a physician, whom to quarantine, and such services of a physician could not be procured without pay. The right of the duly constituted county authorities to employ a physician in an emergency of this kind seemed to the court to come clearly within the express authority given to the county to provide and enforce regulations in order to prevent the introduction and spread of contagious diseases, and that the examination and diagnosis necessary for purposes of quarantine of contagious diseases is one of the regulations contemplated and intended to be covered by the statute. When a person performs services of such kind for the county he, of course, ought to be allowed to recover from the county though the individuals examined and quarantined were not paupers nor a county charge.—*Bartlett v. Dahlsten et al.*, Nebraska Supreme Court, 178 N. W. 636.

MEDICAL RECORD.

THE EFFECTS OF CHRONIC INTESTINAL STASIS.

THE products of digestion and the bacteria and toxins which accompany them are absorbed in the small intestine, cecum, and ascending colon. By the intermediary of the portal vein, they then pass into the liver, which plays in relation to these products, a modifying, antitoxic, and antiseptic part; a certain number of bacteria and toxins are destroyed or transformed into inoffensive substances for the tissue they are to circulate through. They are then eliminated or destroyed without danger to the excretory organs—kidneys, lungs, skin, thyroid—but the overwork put upon these organs finally ends in irritation, inflammation, destruction of the glandular elements, and their functional insufficiency. Thus a portion of the colon bacilli eliminated by the bile infect the biliary tract, hence catarrhal and calculous cholecystitis. The calculi are due to the precipitation of the bile salts which collect around the desquamated epithelial cells. Injection of the embryonal radicles around the canaliculi, an embryonal tissue which may change into fibrous tissue, explains the origin of biliary cirrhosis without either alcohol or malaria playing any part in the process. This chronic irritation of the liver and gall-bladder may end in cancer of these viscera in susceptible individuals, since cancer, here as elsewhere, is prone to develop in chronically irritated organs.

Like the liver, the thyroid transforms a portion of the toxins coming from the intestine and if the gland is overworked, irritated, or inflamed as a result of chronic stercoræmia, its secretions either diminish or become exaggerated in quantity, hence hypo- or hyperthyroidism. Lane assures us that chronic stercoræmia exercises a marked influence on the pathology of the thyroid and he considers that the goiter of Basedow's disease, as well as parenchymatous goiters are frequently the consequence of chronic intestinal stasis. He has shown that colectomy or ileosigmoidostomy modifies the evolution of exophthalmic goiter. This opinion has been corroborated experimentally by MacCarrison. The endocrine glands—suprarenals, hypophysis—have an action on the intestine; on their side, the intestinal

toxins exercise an action on the parenchyma of these glands whose function thus becomes excited or is rendered insufficient by chronic stercoræmia. The skin is pigmented in the flexor folds of the limbs, around the base of the neck, eyelids, perineum, etc.

Chronic stercoræmia may produce chronic mastitis and cystic disease of the breast, according to Pauchet and others, these processes in turn favoring the development of cancer, and this observer states that he has found these women with chronic mastitis or adenoma of the breast suffered from chronic intestinal stasis. Therefore in surgical affections of the female breast it is well to radioscope the digestive tract. It would appear that chronic pancreatitis is frequent in chronic intestinal stasis and often coincides with angiocholitis, and simple or calculous cholecystitis. This chronic pancreatic process, readily recognized at the time of operation on the digestive tract, may at length lead to cancer of this gland. It is probable that carcinoma of the head of the pancreas is, in most cases, preceded by a period of pancreatitis. The skin eliminates sweat overlaid with intestinal toxins, with the result that it becomes thickened in certain areas and as hard as leather. The posterior aspect of the forearms especially is covered with acne, the hair grows in excess on the limbs, and on the contrary falls out on the scalp. The sweat of the axillæ is offensive. There is no question but that dysmenorrhea, amenorrhea, and sterility are common in women with chronic intestinal stasis. Agnèsia is the rule, especially in brunettes. It is difficult to say whether this is due to a direct action of the toxins on the ovaries or to the action of these toxins on the thyroid whose physiological relations with the genital system are so intimate. What is clear is the disturbing action of chronic intestinal stasis on the sexual life of women.

Do the intestinal toxins act directly on the nerves, producing neuralgia, psychic depression, fatigue, or is this general asthenia the consequence of the intestinal stasis on the thyroid, suprarenals, and other endocrine glands? It is possible that both modes of action exist, but what is certain is that treatment of the stasis will cause the patient to regain his vitality.

INFECTION CONVEYED BY MANICURES.

WE are unable to recall any published cases of infection at the hands of manicures in this country, although the aseptic precautions carried out by the manicure of to-day rather suggest that infection following the act was formerly common enough. But Doctor Körbl of Vienna (*Wiener klinische Wochenschrift*, Feb. 5, 1920, xxxiii., 6) has recently made notes of thirty-two cases of the type that may at times constitute a menace to life. As his practice is not a very large one, he thinks that so many cases must argue for the great frequency of such infection, despite the precautions which the manicure is supposed to take. The material was as follows: Two cases of simple felon which readily yielded to treatment; four cases of

paraungual felon which required somewhat longer to heal but were not dangerous; two cases of subungual felon which naturally were long in healing; seven cases of felon involving the tendons, requiring an average of five weeks for healing; five cases of bone felon in which three ended in necrosis of the phalanx with tedious healing, and four cases of joint felon with more or less ankylosis and the loss of one finger. In addition there were two cases of phlegmon of the hand with general septic phenomena, one case of phlegmon of the arm ending in recovery, another case of the same requiring amputation of the forearm, one case of erysipeloid and three of general erysipelas. Naturally in all of these cases the infection began as a phlegmon. This brief summary gives an imperfect idea of the actual amount of suffering and disability, temporary and permanent, which resulted from these infections. In the absence of prompt and timely treatment the outcome would have been far worse. The ordinary felon does not pursue so serious a course and the material was decidedly atypical.

The author asks why this unusual course came to pass and finds the answer ready—it results from pushing down the delicate membrane at the base of the nail with the orange stick and from the attempts to trim it with scissors. In this way a pocket is furnished for the reception of infected matter. Numerous very small punctures are made through the nail and into these are rubbed the pastes and powders of the craft, during which considerable force is used. Deep infection is therefore favored and this accounts for the subungual and tendinous cases. The infection was so virulent that the author made bacteriological studies and found that the staphylococcus was seldom present, but instead a mixture of streptococci with anaerobes including the *B. coli*. There were several cases of pure streptococcus infection, not counting the cases of erysipelas. Primary and secondary infection may be isolated, of which the first is directly chargeable to the manicure. She sometimes passes an infection along from person to person, evidently through imperfectly sterilized instruments. There was a small series of such transmissions and four were simultaneously infected by the same tools. This phenomenon has also been seen in self-manicuring. But since alcohol is freely used in sterilizing the instruments, the author examined the nail ointment of one operator and found in it a pure culture of the streptococcus.

THE TREATMENT OF EPILEPSY BY BORON MEDICATION.

MARIE, Crouzon and Bouttier have methodically studied the results obtained in the treatment of epilepsy with the salts of boron, which suggest the advisability of reviving this form of treatment. This medication has been found by these observers to be quite as effective as the classical bromide treatment from the viewpoint of decreasing the number of seizures, as well as their intensity. Among the

salts of boron they particularly recommend as giving the best results, sodium borate and potassium tartrate—cream of tartar—which until recently has had the reputation of being a purgative drug. They exhibited it in doses of three grams in a watery solution in twenty-four hours.

The decrease in the number and violence of the seizures is already notable after eight or ten days' treatment and continues to become more and more accentuated. Thus, in the more serious cases treated by these observers, the number of seizures was reduced to about thirty-three per cent. during the first three months of treatment, and ultimately completely disappeared with continued medication.

The great advantage of sodium borate and potassium tartrate in epilepsy appears to the absence of all the untoward effects which are so common in bromide medication. There is no mental depression, and there are no gastrointestinal disturbances or cutaneous eruptions, such as acne. Even when this salt is exhibited for months, the patients do not complain of any distress, and for this reason, they willingly continue the treatment.

Marie and his collaborators do not, unfortunately, give any data in respect to the *modus operandi* of borax and cream of tartar, they merely affirm that the action is different from that of the bromides. Now, it is known that the latter salts act especially by decreasing the reactions of the central nervous system and hence results the weakening or disappearance of the tendon, cutaneomucous, and even the pupil reflexes. Nothing like this is to be noted during treatment with the boron salts. And these observers add that the doses of boron or bromine contained in three grams of the salt are very different. Three grams of borax and potassium tartrate contains fifteen centigrams of boron, while the amount of bromine in three grams of potassium bromide is at least two grams.

Boron medication also offers the advantage of being easily given without any trouble to children and elderly subjects, while the epilepsy is quite as favorably influenced in them as in adults.

BASELESS CRITICISM OF THE U. S. P. H. S. HOSPITAL AT FOX HILLS, STATEN ISLAND.

RECENTLY, for some unknown reason, the *Evening Post* of this city has published a number of attacks on the administration of this hospital, on the resident staff, and particularly on Dr. J. C. Cobb, the medical director. These attacks have been so persistent as to cause one to wonder what their origin might be, and the members of the consulting staff, Drs. Robert Kingman, S. Adolphus Knopf, Alexander Lambert, and Arthur McGugan, have now issued a statement declaring them to be malicious and unjust and without foundation in fact. These gentlemen assert that during their visits to the hospital and on interrogating the patients there, they have not heard a single complaint justifying such statements as lack of surgical or medical attention, insufficient or bad food, cruel or harsh treatment on the part of orderlies, guards, nurses, or physicians. The sanitary conditions are such as are found in

all well equipped and well managed military hospitals. In regard to the present condition of the Hospital, it should be borne in mind that Fox Hills was constructed in 90 days by the Army as a temporary evacuation hospital, and when a time was appointed for giving it up no attempt was made to leave the place in a general state of repair. There were about 3,000 panes of glass broken when the U. S. Public Health Service took possession of the hospital, and it has cost close on to \$5,000 merely to replace the broken beaver board in the walls and ceilings. In spite of the lack of repairs, the Public Health Service had no alternative but to take the plant as an emergency hospital pending the construction of a permanent hospital in the metropolitan zone, for which Congress has now made a suitable appropriation. In reference to the complaint of an insufficient staff of nurses and doctors, the physicians mentioned assert that there has never been a time since the hospital became a part of the U. S. Public Health Service that a ward was without the supervision of a trained nurse, regardless of the great and unexpected influx of patients, and this notwithstanding the shortage of nurses all over the United States, not only in Army, Navy, and Public Health Service hospitals, but in civilian hospitals as well. The nurses at Fox Hills are well paid, receiving \$80 to \$85 per month, including board, laundry, etc., and those in the service are satisfied and contented. There are always 40 to 45 resident physicians in attendance. In view of the fact that the 1,200 ex-service men are no longer under military discipline, it is inevitable that there will occasionally be disturbance caused by men coming in late, and even once in a while coming in intoxicated. Such matters are usually satisfactorily settled by the morale officer. The assertion published in the *Evening Post*, that Dr. Cobb had said the patients at Fox Hills are drunkards, thieves, and dope fiends, is characterized in the statement of the consulting staff as willfully false. Other statements criticising the treatment of shell-shock and other nervous cases, venereal cases, and the tuberculous are also shown to be without any foundation in fact.

A EUNUCH ON TESTICULAR GRAFTING.

REGNAULT reproduces in *La Presse Médicale* of February 2, 1921, xxix, 10, a letter from a prominent eunuch of Constantinople in which the latter mentions the work of Regnault and Hikmette, published in 1901 in the transactions of the Anthropological Society on "The Eunuchs of Constantinople." After a word of praise for this work, the correspondent refers to the recent book entitled "Moyens de relever l'énergie vitale et de prolonger la vie." This latest Parisian novelty had been recommended to him by his book seller. Having read it he pronounces it a mixture of fact and fiction, in which the errors predominate over the truth. The similarity between the Brown-Séquard doctrine and the present one is startling. The theory is one thing and the practical application another. Some who injected saline solution as testicular extract got the same result as when the real thing was injected. In other words suggestion plays a rôle. The eunuch admits that by the newer implantation method

castrates have acquired beards and a deepening of the voice—in fact all of the secondary sexual characters of the male have been made to appear or return; but it is a far cry from these changes to increase of vital energy and longevity. The results of grafting on the sexuality are often short-lived. On the other hand does the castrate really lose energy? How about the draught horse and the ox who pull heavy loads all day? How about the energy of the worker bee, which has no sexuality? In regard to eunuchs they are not all soft and effeminate; often they are men of great executive ability. In old Byzantium the executive and administrative offices, including military, the diplomatic positions, etc., were held by eunuchs. Absence of sexuality allows them to concentrate on their work and they are proof against feminine intrigue, while at the same time having an intuitive knowledge of the feminine mind. As for longevity, the correspondent said he could show the new longevity experts many eunuchs over 80 years of age in his home city.

News of the Week.

Dose-fixing by Layman.—Dr. Donald McCaskey of this city, who has been cited by Federal Prohibition Director Charles R. O'Connor to appear on April 7 and show cause why his permit to prescribe liquors should not be revoked and canceled, has announced his intention of carrying the contest to the highest court in the event of adverse action on the part of the judges in Director O'Connor's office. Dr. McCaskey will base his contest on the ground that the limiting of the amount of whiskey a physician might prescribe to one pint every ten days is not authorized by the Eighteenth Amendment. Whether one regards the prohibition amendment with favor or otherwise is aside the question, for it is intolerable that a lay person should presume to limit the dosage of a drug which the physician may find indicated in any particular case.

France Makes Physical Training Compulsory.—The French Chamber of Deputies unanimously adopted a bill on March 22, making physical training compulsory for young people of both sexes. Boys over sixteen years of age must continue physical training, consisting of gymnastics, running, tennis, and other athletics, according to choice, until they are incorporated into the army or navy. Girls in the primary and secondary tuition grades must also adopt physical culture, according to special rules to be issued by the Ministry of Public Instruction.

Influenza Hits Rhine Army.—A severe type of epidemic influenza has broken out among soldiers belonging to the United States occupational army stationed near Coblenz. The Second Battalion of the Eighth Infantry has been quarantined by the medical authorities. Forty-five cases of the disease have been reported.

Medical Service By Airplane.—The French Government has just built six airplanes for use in the colonies, where the distances that doctors have to travel are enormous and where there are no railroad facilities. The planes carry complete medical and surgical kits, and are constructed like ambulances, so that patients seriously ill or injured may

be conveyed from remote regions to hospitals. Most of these planes will go to the African colonies.

Pneumonic Plague Adds to Famine Horror.

Pneumonic plague has recently made its appearance in twenty villages along the border between the provinces of Chihli and Shantung. The epidemic is being controlled by stopping all traffic through infected areas and the isolation of persons who have been stricken. There was a small outbreak in Shantung, but strict measures were enforced in four villages where the plague appeared which seem to have been effective in averting an epidemic. Chihli is in a famine district, where it is estimated that deaths from famine average from three hundred to one thousand daily.

Smallpox Epidemics in the United States.—A smallpox epidemic is causing considerable excitement in Athens, Ga., and has aroused the people to much concern as to the necessity of having someone directly in charge of the situation. The commissioners of Limestone county, in which Athens is located, have voted \$5,000 for the purpose of employing a regular health officer for the county, provided the city of Athens votes \$2,500 for the same purpose. A number of cases of smallpox in light form have been reported from Geneva, Wis. West New York, lying west of Union Hill, N. J., where eight cases of smallpox were reported during the week ending March 19, reports two additional cases. The New Jersey State Health Department is continuing its campaign to have the people of the community consent to vaccination.

Small Banknotes Carry Millions of Germs.—A demand that the French Government replace small banknotes put in circulation some months ago, and which have reached a stage of dissolution and filth, has led to a laboratory examination of a few of these bills. The laboratory reports that a one franc note carried 236,900,000 germs, and two fifty-centime notes 69,480,000 and 90,880,000 germs, respectively.

Dr. Hubert Work of Pueblo, Colo., president-elect of the American Medical Association, has been appointed by President Harding first assistant postmaster general.

Gifts to New Sydenham Hospital.—The fund for the rebuilding of the Sydenham Hospital on its present site in East 116th Street has been increased by a pledge of \$100,000 from an anonymous donor. A gift of \$25,000 has come from Leon Schinasi. The new hospital is to have one hundred rooms, and will receive patients without regard to race, creed, or color.

Violent Deaths Decrease in New York City.—In his annual report to the Mayor, Dr. Charles Norris, Chief Medical Examiner, shows that there was a decrease last year in the number of violent deaths in the city compared with the totals in 1918 and 1919. The total number of violent deaths in the five boroughs in 1918 was 6,200, of which 1,415 were autopsied; in 1919 the total was 4,709, with 1,462 autopsies; in 1920, the total was 4,519, with 1,688 autopsies. Automobiles and automobile trucks caused 692 deaths, 50 per cent. of these being children under thirteen years of age. More than 50 per cent. of all these accidents were due to carelessness in crossing streets. The number of deaths from wood alcohol decreased from 54 in 1919 to

19 in 1920. Dr. Norris in his report asks that a special judicial clearing house, or homicide court, be founded in connection with cases of death by criminal violence or by casualty or highway accidents.

Vital Statistics in New York State for 1920.—The February *Bulletin* of the New York State Department of Health reviews the records of 1920, which show that there were registered in the entire State of New York 233,016 births and 143,767 deaths, these giving a birth rate of 21.1 and a death rate of 13.0 per 1000 total estimated population. The average death rate for the five-year period 1913-1917 was 14.7. Among the important causes of death, those which show rates above the 1913-1917 average are influenza 59.2, measles 9.9, whooping cough 9.1, cancer 94.6, and automobile accidents 12.6. This death rate from automobile accidents is more than double that of the five years 1913-1917. Among those causes of death which show a decrease in rate below the five year average are infantile paralysis 0.6, lobar pneumonia 80.7, bronchopneumonia 67.8, typhoid fever 3.3, cerebrospinal meningitis 1.8, cerebral hemorrhage 60.5, organic heart disease 203.2, diarrhea and enteritis (under two years) 41.9, cirrhosis of the liver 6.9, acute and chronic Bright's disease 104.9, congenital malformations and debility 63.9, and pulmonary tuberculosis 99.1, these rates being per 100,000 of the population. The infant mortality rate for 1920 is 86.9, a decline of more than 10 per cent. from the five year average. The death rate of 99.1 for pulmonary tuberculosis is 30 per cent. below the five year average.

Seventh Day Adventists Hold Medical Meeting.—Officials and attendants at Seventh Adventist sanatoriums east of the Rocky Mountains held a six-day medical convention at the Washington Sanatorium, in Takoma Park, beginning on March 22. The president of the conference, Elder A. G. Daniels, in his opening address, emphasized the importance of the medical feature of the Seventh Adventist movement and of the relief of physical suffering as a part of their work for the betterment of humanity.

Soldier Hospital Board Appointed.—Secretary of the Treasury Mellon has appointed the following board of medical men to determine the type and location of hospitals to be established to care for disabled ex-service men: Dr. William C. White of Pittsburgh, Dr. Frank S. Billings of Chicago, Dr. Pierce Bailey of New York, and Dr. W. G. Bowman of Pittsburgh.

Dr. William A. Bryan, formerly assistant superintendent of the Danvers State Hospital, has been appointed superintendent of the Worcester (Mass.) State Hospital to succeed the late Dr. Ernest V. Scribner, deceased.

Dr. B. G. Burden has been appointed chief resident physician of the University Hospital, Philadelphia.

Dr. C. B. Hussey of Franklin, Mass., has been elected to the managing board of the Milford Hospital.

Madame Curie Honored.—The National Institute of Social Sciences announces that its gold medal has been awarded to Madame Curie in recognition of her discovery of radium and its subse-

quent benefit to humanity. Nine medals have been awarded since the founding of the institute in 1912. These have been bestowed upon Dr. William C. Gorgas, Dr. Abraham Jacobi, Dr. Michael I. Pupin, Dr. George W. Crile, Dr. William J. Mayo, Dr. William H. Welch, Dr. Alexis Carrel, Herbert Hoover, and Vice-President Calvin Coolidge.

The Norwegian Lutheran Hospital Association, at its annual meeting at Minneapolis, Minn., March 10, 1921, elected the following officers for the ensuing year: *President*, Dr. A. O. Funkalsrud, Fargo, N. D.; *Vice-President*, Dr. E. O. Gjere, Watertown, S. D.; *Secretary*, Miss B. S. Anderson, Austin; *Treasurer*, J. E. Haugen, St. Paul.

To Broaden Scope of Gorgas Institute.—Plans to broaden the scope of the Gorgas Memorial Institute in Panama into a research and teaching institution of international scope are being developed by a provisional board of directors for the United States. Admiral Braisted announces that, in accordance with instructions received from President Porras of Panama, the cooperation of American Medical colleges as well as foreign countries is being enlisted. Permanent headquarters of the American Board of Directors have been established at the Pan American Union building in Washington, D. C. When the preliminary organization is completed, three American physicians will be sent to Panama to put the plans into effect. One medical officer of the Army, one of the Navy, and one of the United States Public Health Service will be stationed first at Santo Tomas Hospital in Panama, where they will begin research work in tropical medicine under the superintendency of the hospital. Later the institute will have its own buildings adjoining the hospital.

Kelly-Butte Has New Hospital.—A new municipal isolation hospital has been erected at Kelly-Butte, Ore., at a cost of \$56,000. The hospital has sixty beds and provides for the care of all contagious diseases except smallpox.

Cancer Increasing in Paris.—Statistics recently made public in Paris show that deaths from cancer have increased from 3,073 in 1910 to 3,619 in 1919, and since that time the death rate from cancer has continued to rise. In view of these facts the Municipal Council of Paris has purchased two grams of radium for 2,500,000 francs, which will be used in fighting the ravages of cancer.

Measles in Greenwich.—Reports from Greenwich, Conn., state that this town is leading all others in the State in point of the number of cases of measles. A total of sixty-six cases are at present under treatment for the disease.

Appeal for Soldiers' Hospital.—Cornelius W. Wickersham, chairman of the American Legion investigating committee which has been holding hearings in New York City in the matter of caring for wounded and disabled soldiers, has written to Governor Miller urging that the State of New York proceed to the erection of a State Military Insane Hospital at Creedmoor. An appropriation of \$3,000,000 was made for the purpose last year by the Legislature. Provision was also made for the Federal Government to reimburse the State in ten annual instalments, but the Secretary of the Treasury under the Wilson administration refused to sign the contract, and a Senate committee later

refused to report favorably upon it. As a consequence the hospital project has not progressed.

Buy Paris Hospital Site.—The Board of Directors of the American Hospital in Paris has bought a site for a new building near the present hospital. Plans for a new hospital building with one hundred beds are being drawn by C. C. Knight, an American architect. The building fund, which now amounts to 3,750,000 francs, will be increased to 7,000,000 francs, and an endowment fund of 4,500,000 will be provided.

Government Plans War on Port Rats.—Surgeon-General Hugh S. Cumming of the United States Public Health Service has appointed a commission headed by Dr. H. J. White to visit New York and Boston for the purpose of studying and reorganizing the quarantine service in these cities. After an investigation recommendations will be submitted to the United States Public Health Service. Special attention will be given to the matter of rat proofing. Other members of the commission are Dr. Glover, Dr. A. J. McLaughlin, and Assistant Sanitary Engineer E. C. Sullivan. The New York City Department of Health will cooperate with the Federal authorities in its war on rats.

Medical Society Elections.—THE LENOIR COUNTY MEDICAL SOCIETY, at its meeting in Kingston, N. C., March 15, 1921, elected the following officers: *President*, Dr. Zebulon V. Mosely; *Vice-President*, Dr. M. L. Carr; *Secretary and Treasurer*, Dr. Charles P. Mangum.

THE UTICA (N. Y.) MEDICAL SOCIETY, at its annual meeting, March 7, 1921, elected the following officers: *President*, Dr. E. R. Evans; *Vice-President*, Dr. D. E. Pugh; *Secretary-Treasurer*, Dr. A. M. Johnson.

THE JACKSON COUNTY MEDICAL SOCIETY, at its meeting in Newport, Ark., March 12, 1921, elected the following officers for the ensuing year: *President*, Dr. O. A. Jamison, Tuckerman; *Vice-President*, Dr. H. O. Walker, Newport; *Secretary and Treasurer*, Dr. Ira H. Erwin.

THE SOUTHWESTERN RURAL MEDICAL ASSOCIATION and the Lafayette Medical Association, at its meeting in Lafayette, La., March 13, 1921, elected the following officers for the ensuing year: *President*, Dr. A. R. Trahan; *Vice-President*, Dr. J. P. Franquez; *Secretary and Treasurer*, Dr. R. D. Voorhies.

THE PANHANDLE MEDICAL SOCIETY, at its meeting in Amarillo, Tex., March 16, 1921, elected the following officers: *President*, Dr. J. D. Hutchinson, Lubbock; *First Vice-President*, Dr. A. H. Lindsay, Amarillo; *Second Vice-President*, Dr. Everett Jones, Wichita Falls; *Secretary*, Dr. J. J. Crume, Amarillo.

THE CARROLL COUNTY (TENN.) MEDICAL SOCIETY, at its meeting in Huntingdon, Tenn., March 11, 1921, elected the following officers: *President*, G. C. Bryant, McMoresville; *Vice-Presidents*, Dr. A. T. Dennison, McKenzie, and Dr. Roy A. Douglas, Huntingdon; *Secretary*, Dr. H. J. Williams, McKenzie.

THE YUKA (CAL.) MEDICAL ASSOCIATION reorganized on March 3 and elected the following officers for the ensuing year: *President*, Dr. Roy Jones; *Secretary-Treasurer*, Dr. Robert Heaney.

Obituary Notes.—Dr. JOSEPH J. FERGUSON, a graduate of the University of Nashville Medical

Department in 1903 died at his home in Greenville, Miss., on March 18, at the age of sixty-three years.

Dr. JOHN H. SPITLER, a graduate of the Medical College of Ohio, Cincinnati, 1879, died on February 21, at the age of sixty-nine years.

Dr. HENRY BENJAMIN WILSON, at one time professor of physiology in the Chattanooga (Tenn.) Medical College, a graduate of Bellevue Hospital Medical College, in 1887, died from heart disease, on February 27, at the age of sixty-four years.

Dr. CHARLES WAAGE, the oldest resident of Pennsburg, Pa., and the oldest alumnus of Jefferson Medical College, died of uremia on March 7 at the age of ninety-three years. Dr. Waage was graduated from Jefferson Medical College in 1849.

Dr. WILBUR A. BUMPS, a graduate of New York University Medical College in 1879, died after a lingering illness at his home in Dexter, Me., on March 11, at the age of sixty-seven years.

Dr. ERNEST LLEWELLYN WRENTMORE of Chagrin Falls, Ohio, a graduate of the Western Reserve University in 1900, died of heart disease on February 23, at the age of forty-seven years.

Dr. DANIEL P. WHITLEY of Albemarle, a graduate of the University of Maryland School of Medicine in 1889, died on March 7 at the age of fifty-five years.

Dr. N. M. PALMER, a graduate of Vanderbilt University, Nashville, Tenn., in 1907, died at his home in Shreveport, La., on March 7, at the age of 41 years.

Dr. HENRY OSBORNE BEATTIE of Pittsburgh, Pa., a graduate of the Royal College of Physicians and Surgeons of Dublin in 1883, died on March 14, at the age of sixty-one years.

Dr. GEORGE H. DAVIS of Upton, Wyo., died of typhoid fever in New Mexico, where he had gone to superintend the construction of hospital of which he was to be superintendent on February 27. He was a graduate of the Sioux City College of Medicine in 1905.

Dr. DAVID M. CURRIER of New Port, N. H., died at his home on March 1 at the age of eighty-one years. He was graduated from the Medical Department of Dartmouth College in 1867.

Dr. JESSE H. HUGHES of Nanticoke, Pa., a graduate of New York University Medical College in 1892, died of pneumonia on March 5.

Dr. B. R. O'CONNOR, a graduate of the Philadelphia University of Medicine and Surgery in 1867, died at his home in Petaluma, Kan., on February 26 at the age of eighty-four years. He formerly practiced medicine in Grenola, Kan.

Dr. JOSEPH CONN of New Orleans, La., a graduate of Tulane University in 1897, died suddenly on March 4 at the age of fifty-one years.

Dr. G. E. MUIR, a graduate of the University of Louisville Medical Department in 1894 died at his home in Pawnee Rock, Kan., on March 12, at the age of fifty-two years.

Dr. ROBERT H. CHASE died suddenly at his home near Wyncote, Pa., on March 13, at the age of seventy-five years. He was graduated from the University of Pennsylvania in 1869. He was formerly connected with the Government Hospital for the Insane at Washington, D. C., and later was superintendent of the State Hospital for the Insane at Norristown, Pa. He was a member of the Amer-

ican Medico-Psychological Association, the Neurological Society of Philadelphia, the Philadelphia Medico-Legal Society, and the Philadelphia Medical Club. He was the author of several books on insanity.

Dr. CHARLES A. ELLIS of Denver, Colo., a graduate of the University of Buffalo Medical Department in 1891, died on March 7, at the age of fifty-three years.

Dr. JOHN M. FULLER, the oldest physician of Uniontown, Pa., died at his residence on March 12, at the age of seventy-seven years. He was a graduate of Jefferson Medical College in 1864.

Dr. G. H. POST of Fithian, Ill., a graduate of the Eclectic Medical College, Cincinnati in 1875, died on March 9.

Dr. HENRY C. CARROLL of Chicago, Ill., retired died at Canandaigua, N. Y., on March 6 at the age of seventy years.

Dr. JULIUS C. EGEGER, assistant chief surgeon of the San Francisco Emergency Hospital, a graduate of Cooper Medical College in 1905, died on March 8 at the age of forty-five years.

Dr. JULIUS SCHOENITH of Detroit, a graduate of the old Michigan Medical College, died of cerebral hemorrhage on March 6 at the age of seventy years.

Dr. HENRY W. A. PACHMANN of Hurlburton, N. Y., a graduate of Bellevue Hospital Medical College in 1894, died suddenly of heart disease on March 5, at the age of fifty-nine years.

Dr. W. E. MORGAN of LaGrange, Ga., a graduate of the Atlanta College of Physicians and Surgeons in 1898, died from pneumonia on March 9, at the age of forty-five years.

Dr. HAYDON ROCHESTER, a graduate of New York University and Bellevue Hospital Medical College in 1902, died in San Francisco, Cal., on March 13, at the age of forty-two years.

Dr. PETER P. VAN VLEET, a graduate of Bellevue Hospital Medical College in 1872, died at his home in Stamford, Conn., on March 12, at the age of seventy-four years.

Dr. JOSEPH TABER JOHNSON of Washington, D. C., and Georgetown, died at his home in Cherrydale, Va., on March 13, at the age of seventy-five years. He was graduated from the Georgetown Medical School in 1867, and became professor of obstetrics in Howard University. He became president of the faculty of Georgetown University Medical School in 1874. He was president of the American Gynecological Society in 1898 and also a president of the Southern Surgical and Gynecological Association.

Dr. E. L. LEONARD, a graduate of the Starling Medical College, Columbus, Ohio, in 1892, died at his home in Fulton, Ohio, on March 7, at the age of fifty-seven years.

Dr. AUGUSTUS W. TURNER, a graduate of the College of Physicians and Surgeons, Boston, died of heart disease in that city, on March 10, at the age of sixty-seven years.

Dr. LUTHER M. HALSEY of Williamstown, N. J., died from uremia on March 22 at the age of sixty-three years. He was a graduate of Jefferson Medical College, Philadelphia, in 1880. He served as president of the New Jersey State Medical Society in 1918, and was also president of the Gloucester County Medical Society.

DR. PETER M. VANDENBERG of Grand Haven, Mich., a graduate of the Michigan Homeopathic Medical College, Lansing, in 1894, died at his home on March 18.

DR. ADELBERT ALLEN JOHN of Oregon, Ill., a graduate of the Northwestern University Medical School, in 1898, died from carcinoma in a Chicago hospital on March 1 at the age of sixty-five years.

DR. REGINALD STONESTREET, a graduate of Vanderbilt University Medical Department, in 1891, died after a long illness at his home in Nashville, on March 18, at the age of fifty-six years.

DR. JOSEPH H. MACDOUGAL of Middletown, Conn., a graduate of the New York Homeopathic Medical College, in 1877, died suddenly of heart disease, on March 21, at the age of sixty-six years.

DR. FLORA L. S. ALDRICH, a graduate of the Minneapolis Hospital Medical College, in 1887, died after a brief illness at her home in Anoka, Minn., on March 19.

DR. WILLIAM A. KOHLMAN of New Orleans, a graduate of the University of Würzburg, Germany, in 1891, died of heart disease, on March 22, at the age of fifty-six years.

DR. HERBERT J. KNAPP of Brooklyn, N. Y., a graduate of the New York Homeopathic Medical College in 1884, died in a local hospital, on March 25, at the age of fifty-six years.

Correspondence.

THE PROFESSIONAL GUILD OF KINGS AND QUEENS COUNTIES.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—I have read with great interest the MEDICAL RECORD of March 12, with especial reference to the various notes on medico-legislative matters, as well as the editorial supporting the Lord Bill and the communication of Dr. John J. A. O'Reilly, a distinguished advocate of sane legislation in medical matters.

Specifically, the Burlingame bill was mentioned as having had a hearing with but very little opposition. The facts are that the Burlingame bill was designed to restore to the working man of this State *free choice of doctor and druggist* and that the opponents of the measure outnumbered the proponents in the ratio of 3 to 1. The encouraging phase of the hearing was that the State Federation of Labor endorsed and, through its representative, Mr. O'Hanlon, supported the bill. Insurance carriers and corporate interests opposed it as well as the State Industrial Commission through Commissioner Sayer, who stated that those active in behalf of the measure were undoubtedly "lodge doctors and ambulance chasing doctors."

The truth is that the Professional Guild of Kings and Queens Counties introduced the bill, and the Guild is not an organization of "shysters" but one of doctors, druggists and dentists, endeavoring so far as they can not alone to prevent further oppressive and restrictive legislation but to undo the wrongs of the past. The Guild will introduce the bill again at the next session and hopes to enlist the cooperation of all the scientific societies in the State, together with other lay organizations.

The Lord Bill, in the support of which your editorial displayed a keen insight into the whole narcotic question, was also introduced by the Guild. The mass meeting at which the Deputy Commissioner of the State Narcotic Commission was present was referred to by Dr. O'Reilly, who omitted mentioning that it was held under the auspices of the Guild.

May I further state that the Guild has begun proceedings seeking to enjoin the Commissioner of the State Narcotic Commission from enforcing the regulations issued in December, 1920? As to the success of the action there is some doubt, but we feel that the time has come for a show down.

The issue is plain, the conclusions inescapable. The practice of medicine and its allied professions, pharmacy and dentistry, hangs in the balance. In one form or another we are called upon to face legislative forays each year and the answer to them is *Organization*. The Professional Guild is the answer of Kings and Queens Counties. How long will it be before the other counties of the State join us in the effort to save the public from the kind of medicine which will exist if legislation, present and threatened, becomes statute?

FRANK D. JENNINGS, M.D.

1083 BUSHWICK AVENUE,
BROOKLYN, N. Y.

RUPTURE OF THE UTERINE ARTERY.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—In No. 3, Vol. xcix of the MEDICAL RECORD I read with great interest the case described by Dr. John C. Major, "Spontaneous Rupture of the Uterine Artery During Confinement." These cases of hæmatoma vulvæ et vaginae are usually caused by the bursting of *veins*. In the formation of the thrombus, particularly in the formation of the pelvi-abdominal hæmatoma, one of the big peri-uterine venous plexuses gives way. This is the explanation given by the French obstetricians, among them Blot, Cazeaux, Brindeaux and P. Bar. It would be very interesting to know if the normal uterine artery could rupture during spontaneous labor.

HUBERT M. BOSHOUEWS, M.D.

VALPARAISO, CHILE.

OUR LONDON LETTER.

(From Our Own Correspondent.)

LONDON, March 10, 1920

The Influence of Diet on Dentition.—At a meeting of the London Association of the Medical Women's Federation held in London on February 15, Dr. Eva Handley-Read read a paper on the influence of diet on dentition (1) on teeth during the prenatal period (2) on dental caries, (3) on pyorrhea alveolaris. The speaker dwelt upon the importance of accessory food factors as absolutely essential to growth, and of the anti-rachitic fat-soluble A vitamine as a necessity in diet if the hardest tissue of the body and the one requiring the best nourishment, *i.e.* the enamel of the teeth is to develop properly. Owing to the fact that the temporary teeth are fully formed in the jaws before birth and that calcification begins in the sixteenth week and continues through the existence of the teeth, it is evident

that the mother's mode of living during pregnancy and lactation must influence the teeth of the child. Even at the worst war period the diet of the poorest working woman in Great Britain had just enough of essential vitamins to produce bone and tissue fairly well calcified, and observations at baby clinics show that the teeth of all babies erupt fully formed with apparently good enamel, but if the diet is poor in the antirachitic vitamin the enamel is found carious within a few months. It has been shown that the absence of fat soluble A vitamin influences the development of teeth and jaw in puppies, causing (1) Poor growth of bone and alveolar process, the tissue being osteoid. (2) Irregularity of lower incisors. (3) Delayed eruption and shedding. Delay in calcification, poor enamel and dentine and lessened resistance to diseases such as distemper and bronchopneumonia. Pregnant and nursing mothers should have a liberal supply of fat-soluble A in the diet as well as the other vitamins. In reference to pyorrhea alveolaris Dr. Read pointed out that this condition was rampant all over the world among white and colored races and was also common in animals kept in captivity. It seemed probable that an excessive carbohydrate and deficient antiscorbutic diet largely accounted for this. In true scurvy acute periodontitis was a marked symptom and the teeth dropped out if antiscorbutic treatment was delayed. Probably modern diet contained sufficient antiscorbutics to prevent actual acute scurvy but not to prevent a chronic periodontitis. Pyorrhea was present because in the mouth there was damaged tissue in the shape of inflamed gums, due to pap foods; bacteria were always present and with a diet deficient in antiscorbutic vitamins pyorrhea supervened. That many vegetarians suffered from pyorrhea was probably explained by the fact that they were mostly large consumers of carbohydrates and that their vegetables or fruit were rarely eaten raw. In Asiatic races, caries was rare, but the teeth dropped out at middle age in those parts of the country where the antiscorbutic factor was deficient in the diet. Points which led to the conclusion that chronic general periodontitis was really connected with diet were its universality, its development among wild animals brought into captivity, the fact that no specific bacteria had been isolated, and the further fact that some persons who might be considered food cranks had effected their own cure. Dr. Read went on to describe several cases in which she had found acute pyorrhea completely cleared up on a diet of raw vegetables, salads and fruit, and very limited carbohydrates. An "intensive vitamin" diet such as this would produce astonishingly good results. While firmly believing in the efficacy of such treatment for chronic pyorrhea, local treatment by drugs, vaccines, and ionization should not be neglected.

Mental Tests.—Dr. W. A. Potts read a paper at the Section of Psychiatry of the Royal Society of Medicine on February 8, 1921, on mental tests. In referring to such tests the speaker said that one of the strongest arguments for tests came from the American army. Dr. V. V. Anderson of the Municipal Court at Boston, U.S.A., first stated that 10 per cent. of all civilian prisoners were mentally defective and of those 10 per cent. were responsible for 50 per cent. of all crime. When the Americans

came into the war they decided to raise an army of 3,000,000 men. On inquiry into the arrangements necessary for an army of that size, they were informed that experience in previous wars showed that provision must be made in military prisons for 50,000 cases. It occurred, however, to their psychologists that this number might be reduced if all recruits were given a special examination with the object of excluding mental defectives. This was done with the result that there never were as many as 5000 in the American medical prisons, or less than one-tenth of the number expected. The American psychologists, however, did more than that. They extended their examination so that they analyzed the intellectual capacity of the men, and so could estimate what work they were fit for in the army. Having found out previously what amount of intelligence was necessary for any particular line, they were able to point out the men best suited for promotion to commissioned work, and for undertaking work requiring special skill. They also saw to it that each unit had an adequate number of men with more than average intelligence, instead of allowing an accumulation of such men in one place, with a corresponding lack of capable men elsewhere. Not only did they make the best use of their good material and prevent the bad from being a handicap, but they actually made use of many of the defectives by enrolling them in labor battalions and putting them to simple tasks which they could do as well as anyone else. Dr. Potts compared the American methods with the haphazard methods adopted by the British War Office although he thought that many of the American army tests were open to criticism. In discussing the paper of Dr. Potts, Dr. W. H. Coupland said that the great development of tests in America was important, even if the Americans were somewhat too enthusiastic with regard to them. In time the various tests would be more accurately evaluated.

Spahlinger Treatment for Pulmonary Tuberculosis.—Recently the lay papers have been full of eulogistic accounts of a reputed cure for consumption thought out and practised by a Swiss lawyer by the name of Spahlinger. In answer to a question asked in the House of Commons regarding this method of treatment Dr. Addison, Minister of Health said that he had made full inquiries with respect to this supposed remedy for tuberculosis, but that it was clear that much further investigation and experience would be necessary before accepting the claims made for it. It appeared that so long ago as 1913-1914 the serum in question was prepared. It was tried by several hospital physicians, but there was not as yet sufficient evidence of its therapeutic value, nor had the trials of it been sufficiently extensive to justify any definite or reliable conclusions. He understood that a report on the method of treatment had been presented to the French Academy of Science and when supplies of the serum became available for investigation in Great Britain Dr. Addison would be prepared at once to facilitate and cooperate in an exhaustive examination of its efficacy from both the laboratory and the clinical points of view. He understood that a supply of the serum was not likely to be available for some months, and that on account of the secrecy maintained as to its constitution and method of

preparation it had hitherto been found impracticable for the recognized British research laboratories to investigate its properties and effects.

An Appeal by British Pharmacists.—A large number of the old established British Pharmaceutical houses have issued an appeal to medical men of the British Empire to support British industry to the utmost of their power. The following are some of the facts presented and published in the British medical journals: (1) In all fairness it should be realized that international trading is not on a reciprocal basis, that is to say, foreign chemical and pharmaceutical preparations are now admitted into Great Britain, practically speaking, duty free, whilst goods exported from Great Britain to countries abroad are subject to an exceedingly high ad valorem duty. One vast country we have in mind directly prohibits the import of pharmaceutical preparations of other countries, while other immense States do so indirectly by means of the high duty already referred to. (2) It should be remembered that, although much has been done during the war and since in the direction of promulgating British chemical industry, a great amount of work has yet to be done to consolidate the fine chemical and allied industries at home, and an obvious point is that the factories in Germany are for the most part absolutely intact and she retains secrets which are the outcome of laborious, painstaking investigation. (3) We desire to respectfully impress on the readers of the journals in which the appeal is published, that we do not advertise to the public, nor "prescribe," nor in any way trespass on the rightful province of the medical practitioner; on the contrary, we rely on the position that chemistry, so far as the medical use of chemicals is concerned, is the handmaid of the medical man, and we might add rather bluntly, we do not recommend foreign medical men and health resorts; why should the medical man recommend foreign pharmaceutical preparations? (4) The scientific staffs in the laboratories here welcome suggestions from the medical profession and will carry out investigations to elucidate problems connected with chemistry, materia medica, and the like which may prove of assistance in the art of healing. (5) We have in our employment men who have been through the hell of the recent war. We have also with us young pupils and apprentices who had never even heard the name of Lister and who knew nothing of his teaching until we taught them what he did for suffering humanity. Those two types of men in our opinion need every support, encouragement and protection which the medical man can give.

Encephalitis Lethargica.—The Ministry of Health has issued recently a memorandum on encephalitis lethargica. Referring to the diagnosis of this disease it is pointed out that this is very difficult and that various nervous diseases and nervous sequelæ present a clinical picture of close resemblance, but with experience medical practitioners are steadily gaining the necessary acquaintance and insight. As for precautions to be taken to prevent the spread of contagion attention is drawn to the fact that with regard to persons in contact with cases, although the disease has a low infectivity, the patients should be isolated as far as possible and association limited to the needs of nursing. It is stated that there is no necessity to

place restrictions on the movements of other occupants in an infected household save in the case of school children, when, as a precautionary measure, it is recommended that they should be kept from school for at least three weeks after the isolation of the patient. Further, all contacts are advised to use the simple sprays, douches and gargles which were found valuable in influenza.

Treatment of Phthisis.—Sir Richard Douglas Powell gave the Emeritus lecture at the Middlesex Medical School on March 4. In the course of his remarks he said that within the past sixty years there had been a decline of more than one-half in the death rate. The principle of sanatorium treatment, in its attention to food and its insistence on complete rest or different degrees of exercise was right, and if one sometimes heard abuse of sanatoriums, it must be remembered they had been so boomed that too much had been expected from them. He was inclined to think it was a mistake that they should not take in patients except in the early stages of the disease, for it was necessary to deal with instances of it which were beyond the incipient stage; where the disease was active it was not hopeless. What was needed was that hospital should be linked with sanatorium treatment. They had that to a limited extent at the Brompton Hospital, where cases sufficiently favorable to require different measures were passed to Frimley, and in three or four months a man could often do a considerable amount of work and go back to the salary waiting for him. But these patients often required further treatment and the promising scheme was a country village colony on the lines of that at Rapworth Hall, in Cambridgeshire, where men could be given work suited to the stage of their complaint.

National Baby Week Council.—An English-speaking Conference on Infant Welfare will be held at the Kingsway Hall, Kingsway, London, W.C., on July 5, 6 and 7, 1921, from 10-1 and from 2.30 to 4.30 each day. The following will be the main subjects under discussion. (1) Residential provision for mothers and babies. (2) Inheritance and environment as factors in racial health. (3) The supply of milk: Its physiological and economic aspects. Papers will be submitted by a number of authorities from all parts of the world on the above subjects. Their names will be announced in the detailed program which will be available shortly. The papers to be discussed at the Conference will, as far as possible, be printed in advance.

Obituary.—Sir Felix Semon, K.C.V.O., M.D., F.R.C.P., the well-known nose and throat specialist died on March 1, last. Born at Dantzig, the son of a Berlin stockbroker, he began his medical studies at Heidelberg and took his medical degree in Berlin. He then came to London and in 1883 was appointed physician in charge of the department for diseases of the throat at St. Thomas' Hospital and held the post for fifteen years. He soon became a leader of the young men in London interested in diseases of the throat, and when the question arose of founding a society on laryngology, they met at his house where all the arrangements were made for the foundation of the Laryngological Society, of which he was president for three years. During the war Sir Felix Semon was outspoken in his condemnation of the methods of barbarism employed by Germany.

Progress of Medical Science.

1. **Bone Setters, Osteopaths, and Physical Therapies.**—E. H. Bradford advances the view that perhaps the belief among the laity that physicians are bigoted, prejudiced, and not ready to receive the ideas of untutored minds who claim to get results by unacademic methods, may account for the vogue of the bone setter and the osteopath. Owing to the remarkable development of surgery, the demand upon the surgeon for serious operative undertakings has been so great that he is forced to turn from many minor methods of relief. In the days of Ambrose Paré the surgeon dressed wounds empirically. To-day he operates on shielded tissue and leaves repair to the *vis medicatrix nature*. Perhaps the chiropractic practitioner may be right in claiming his title in thinking that the work of the hand properly directed may be of service in restoring function. Of all the unacademized practitioners the "bone setter" enjoyed the best name. There may be surprise that bone setters have been ephemerically supplanted by those using as their appellation the badly coined word, "osteopath." A practice which has been accepted in many communities to the extent of recognition in some States as an authorized method of treatment must have some reason for its existence and acceptance other than novelty. Perhaps the vogue of osteopathy may be, in part, due to a tendency to polysurgery, i.e. excessive operation. A sufferer from rheumatic pains, for example, may naturally prefer to be manipulated by nonmutilating methods than to have all his teeth extracted or his tonsils removed. It is natural that the medical profession should regard irregular methods of practice with some suspicion, for there is much ignorant error in medical matters which is injurious, but to regard the unacademic with contempt is irrational as well as narrow; successful popular remedies may contain a grain of truth. Homeopathy meant that the medical profession should avoid heavy, nauseous, and needless drugging. Christian Science indicates that psychology and a knowledge of the working of subconscious thought are needed in medical practice. The catarrh cures preceded laryngology, cancer cures without the knife pointed the need of cancer research and radium study. A prevalence of osteopathy and bone setting means a need of a more scientific study of physical therapeutics.

5. **Fluoroscopic Bronchoscopy, Esophagoscopy, and Gastroscopy.**—Robert C. Lynch holds that fluoroscopic bronchoscopy is of the greatest aid in the successful removal of long retained opaque foreign bodies from the bronchi or abscess cavities, and it likewise helps as a guide to the site of abscess even when the foreign body cannot be seen. It is an aid in selected gastroscopic cases, and an assistance in establishing a pathway in an impermeable stricture of the esophagus. Seven illustrative cases are briefly reported.

7. **Suppurative Submaxillary Adenitis.**—Benjamin Lipshutz emphasizes the importance of radiographic study in all cases of cervical, facial, and submaxillary adenitis. The external appearance of the teeth gives unreliable evidence of the existing pathological condition. The cooperation of the dental surgeon is indicated for the successful and expeditious treatment of submaxillary, cervical, and facial abscesses which have their origin in dental and periodontal infections.

12. **Qualifications a Peroral Endoscopist Should Possess.**—John W. Murphy places first among the necessary qualifications the possession of a mechanical turn of mind. No two cases are alike, and unless one is quickly able to make changes in one's armamentarium and technique, failure will result. The next important qualification is normal vision. Even a slight error of refraction is somewhat of a handicap, and the presence of a considerable error makes the task almost impossible. A third and very essential qualification of the up-to-date bronchoscopist is that he should have a good surgical training. He should feel as much at home in doing a tracheotomy or an external esophagotomy as he would in doing a tonsillectomy. The fourth and last qualification mentioned is contained in the scriptural injunction: "Now abideth faith, hope, charity: these three; but the greatest of these is charity." One who goes into this work with the expectation of reaping adequate emoluments from it is doomed to disappointment.

2. **The Cerebrospinal Fluid in Treated Syphilis.**—Joseph Earle Moore states that in the routine study of cases in the syphilis department of the Johns Hopkins Hospital, lumbar puncture is regarded as especially indicated in three groups of patients: (1) those presenting on admission evidence suggestive of or permitting a diagnosis of neurosyphilis; (2) all other patients accepted for treatment; and (3) treated patients about to be discharged as presumably cured. The findings are summarized as follows: 1. The cerebrospinal fluid of 642 syphilitic patients in all stages of the disease, but without demonstrable physical evidence of neurosyphilis of any type, has been examined after the administration of from two to six months of antisyphilitic treatment. 2. Of thirty-four patients with primary syphilis in whom treatment was begun before the appearance of secondary symptoms only one (2.9 per cent.) showed an abnormal spinal fluid. 3. After the appear-

ance of secondary symptoms the incidence of abnormal spinal fluid findings was about the same (from 12 to 15 per cent.), no matter how long the disease had existed, or by what lesions it was apparent. 4. Only 12.7 per cent. of these 642 patients showed spinal fluid abnormalities, showing that the amount of treatment administered had been successful in clearing up at least half of the early changes noted by other workers in untreated cases. 5. Asymptomatic neurosyphilis is approximately twice as frequent in white as in colored patients. 6. As minor signs of value in predicting the probability of neurosyphilis are a persistently positive blood Wassermann reaction after treatment, slight pupillary abnormalities, and certain complaints of the patient, namely, headache, nervousness, lassitude, and generalized neuralgic pains. Of 173 patients who showed such signs the spinal fluid was abnormal in forty-nine, or 28.3 per cent. On the other hand, of 469 patients in whom neither these nor other more serious neurologic damage was demonstrable, only thirty-three, or 7.03 per cent., showed abnormal spinal fluids. 7. In general, the serological evidence of symptomatic neurosyphilis can be caused to disappear by prolonged, intensive, routine antisyphilitic treatment. 8. In the syphilis department of the Johns Hopkins Hospital more than 20 per cent. of all patients are clinically, or because of the serological evidence, potentially outspoken neurosyphilitics. The writer maintains that study of the spinal fluid should be carried out as a routine in all syphilitic patients, as an essential to intelligent treatment. Spinal puncture should be performed after the first or second course of arsphenamine, and should be repeated at least once before the patient is discharged as presumably cured. If this is done in every case of syphilis, and treatment intelligently administered according to the results obtained, the incidence of clinical neurosyphilis may be reduced to an absolute minimum.

3. **The Intravenous Use of Corpus Luteum Extract in Nausea of Pregnancy.**—John C. Hirst first began the use of corpus luteum extract by hypodermic injection in the treatment of the nausea of pregnancy in 1915, basing its use on the theory that every woman, during the period of sexual activity, is constantly absorbing corpus luteum. With the onset of pregnancy this absorption ceases. The corpus luteum of pregnancy increases in size, until it reaches its acme about the third month. From this time on it is gradually absorbed. The nausea of pregnancy, beginning during the period of nonabsorption, disappears about the time that the corpus luteum begins to decrease in size. Preparations of the corpus luteum available are: (1) A compressed tablet, containing about 5 grains of the dried substance; (2) powdered extract, and (3) ampules for hypodermic administration, containing 0.2 gm. of the dried substance in solution in 1 c.c. of physiological sodium chloride solution. Corpus luteum may be administered by mouth, by subcutaneous injection, by deep intramuscular injection, or by intravenous injection. The writer considers intravenous injection the ideal method for the following reasons: 1. The material used is carried directly into the circulation, giving the most rapid absorption possible. 2. It is possible and advisable to use a considerably larger dose (two or three ampules) than is possible with the intramuscular injection, in which more than 1 c.c. causes considerable local reaction. 3. Each ampule contains only 0.2 gm. of the extract, and in this way the necessary total quantity can be introduced more easily and quickly. 4. There is no local reaction or discomfort of any kind after the injection. 5. Intravenous administration often controls the vomiting promptly, in cases in which intramuscular use has failed. The dosage varies with the type of case. Anaphylactic reactions need not be feared. The presence of a goiter in early pregnancy absolutely contraindicates the administration of corpus luteum extract, either intravenously or intramuscularly, for the control of nausea. In not a single case, in the writer's experience has there been any rise of temperature or any evidence of infection following the intravenous use of the extract. The results are more gratifying, more prompt, and more lasting than by any other method.

12. **The Neurasthenic Patient and the Internist.**—William J. Mallory emphasizes the point that the

neurasthenic syndrome is a type of reaction which may modify and partly obscure the symptoms of serious physical or psychic disease. Congenital and acquired physical inferiority should be considered important predisposing causes. The immediate cause of such a reaction may be psychic or physical, or both combined. In the treatment, physical deficiency and organic disease should be recognized, and relieved as far as possible in order to aid readjustment on the psychic level.

2. **The Cerebrospinal Fluid in Disseminated Sclerosis.**—Douglas Kinchin Adams gives a résumé of a preliminary report to the Medical Research Council on work done in an experimental investigation into the etiology of disseminated sclerosis. The present communication deals only with the first part of the work, consisting of observations upon the cerebrospinal fluid. It is summarized thus: 1. The cerebrospinal fluid picture in disseminated sclerosis is as follows: a normal cell count, a negative Wassermann reaction, a leucic or paretic reaction to colloidal gold, and in most cases (83 per cent.) a normal protein content. 2. The absence of a positive Wassermann reaction in the great majority of cases and the absence of pleocytosis are in accordance with the view that this disease is not of syphilitic origin. (3) On the supposition that the origin might be spirochetal treatment was carried out by spirocheticidal drugs. In practically every case under treatment modifications toward a negative result of the colloidal gold reaction were noted. 4. As regards clinical effects of such treatment, no improvement resulted in advanced cases of the disease, but prolonged treatment produced amelioration of early cases, and in one or two instances the results were marked. 5. With reference to early diagnosis, emphasis is laid on the evidence of the cerebrospinal fluid picture and the absence of abdominal reflex.

4. **The Skin and Its Reactions.**—Arthur J. Hall, after discussing briefly the duties of the skin outside the body and inside the body, considers the relation of skin diseases to internal disorders. In this connection it must always be borne in mind that the skin is not merely a covering, but itself an important organ; that its duties relate chiefly to events occurring outside the body; that while some of these reactions are local processes in the skin, the bulk of them are controlled and regulated by the central nervous system, and are of the nature of reflex actions; that like all other reflex actions they are capable of excitation from places other than the outside, and of being modified by the condition of the central nervous system resulting from changes in the internal organs. In this sense they must depend upon the condition of the body as a whole at any given time. Greater progress may result if one bears in mind this individuality of the skin as an organ, studying more closely its reactions, than if it is regarded as a kind of screen upon which the clinician views what is going on in the organs beneath. The writer believes that many changes in the skin now attributed to internal disorders are capable of explanation as natural reactions of the skin to definite stimuli. Under this head he considers (1) widespread dermatitis developing during local treatment, as when a patient who is being treated for a trivial local eruption suddenly and unexpectedly develops a widespread acute weeping dermatitis, and (2) acute vesicular dermatitis induced by wearing a necklace, a specific case of which is cited. Under the second category the history is given of a patient who developed a localized dermatitis from wearing an imitation pearl necklace. Investigation revealed the fact that the dermatitis was not caused by friction, but by the irritant action of the wax-like substance with which the individual beads

were filled, and which, when warmed by the body, exuded through the holes where the beads were strung.

6. Stenosis of the Internal Meatus After Suprapubic Prostatectomy. Andrew Fullerton.

1. The Function of the Kidneys in Enlargement of the Prostate Gland.—J. F. Dobson, in this Arris and Gale Lecture, passes over the discussion of prostatectomy for simple enlargement of the prostate, which, in many cases, gives most satisfactory results. Outside of the select cases, as in Freyer's recent series in which the mortality is given as 3 per cent., complications arise which induce a mortality of 15 to 25 per cent. These complications are placed in the following categories: 1. Impaired renal function due to back pressure without infection of the urinary tract. 2. Infection of the urinary tract. 3. Infection with definite impairment of renal function. 4. General organic disease. Brief histories of fifteen patients are given, from which the following conclusions are drawn: 1. The blood urea concentration corresponds very closely with the clinical symptoms. In those cases where the patient was becoming uremic the blood urea concentration was high. 2. Impaired renal function occurs in patients who have no infection of the urinary tract, the renal impairment being due entirely to back pressure. 3. Severe infection of the urinary tract (confined to the bladder) may be present without impaired renal function. 4. The majority of cases of serious infection had impaired renal function. 5. A decided fall in blood urea concentration occurs after cystotomy, in the majority of cases the blood urea figures falling practically to normal. 6. The seriousness of those cases in which the blood urea figures remained high after cystotomy. From the entire consideration of the subject it is held that: 1. Blood urea estimation is a reliable guide to the functional capacity of the kidneys. 2. Its estimation should be carried out in every case of enlarged prostate before operation. 3. Blood urea figures over 25 point to the desirability of a period of preliminary treatment, with drainage of the bladder either by catheter or through a cystotomy wound. 4. If the tied-in catheter is used further blood urea estimations will show whether improvement is taking place. 5. If not, a cystotomy should be done and further estimations carried out. 6. When the blood urea figures fall to under 30 prostatectomy may be done, the general condition of the patient being in other respects satisfactory. 7. In preliminary cystotomy and regular antiseptic instillation we have a method of dealing with cases of impaired renal function, whether due to back pressure only or to back pressure and renal infection. We can estimate the impairment in renal function by estimating the blood urea; we can only estimate the improvement in the infection of the kidneys by ordinary clinical observation. If the blood urea figures are normal, with a badly infected bladder, it is probable that one may assume that the kidneys are not yet infected.

3. Sæmremic Glycosuria.—Charles Gaskell Higginson considers the word "transient," as applied to glycosuria, of the lowest practical and scientific value, for, on the one hand, one could never know that the glycosuria was transient until it was gone, and, on the other hand, the cause of the glycosuria was left undesignated in the teaching that there was such a condition as "transient glycosuria." The words "sæmremic glycosuria," however, have a high value: in diagnosis, for the cause is named; in prognosis, because an early, happy result—life instead of death—is soundly predicted; and in treatment, because common diet may be used and the modern starvation and starch-free diet (a great nuisance) is forbidden. He believes that carbuncle or gangrene secondary to diabetes is not very common, but he readily sees why so debilitating a

disease as diabetes can be, like other forms of debility, a real predisposing cause for carbuncle or gangrene.

(1) In sæmremic glycosuria the sugar is relatively small in quantity. The largest quantity recorded in this paper as having been passed in twenty-four hours is 1,400 grains (or 3 oz.). In diabetes the patient commonly passes from half a pound to three-quarters, say, 4,000 to 6,000 grains daily. (2) Consequently, in sæmremic glycosuria one finds an absence of the great diabetic symptoms—namely, no hunger, no thirst, no emaciation, no polyuria. (2) In the case of sæmremic glycosuria associated with gangrene there will probably be found enough arterial degeneration in the patient to account for the gangrene without it being necessary to fly to the hypothesis of diabetes. As the sæmremic products of gangrene, carbuncle, erysipelas, etc., differ considerably from each other, it is probable that one sæmremia will differ from another in its power of lowering the saturation point for sugar. At present gangrene and carbuncle are the most striking and misleading agents in the causation of sæmremic glycosuria, but further investigation will doubtless reveal a long series of such agents differing from each other very much in the power of causing sæmremic glycosuria.

1. Hypophyseal Insufficiency: Diagnosis and Non-surgical Treatment: Report of Twenty Cases. E. N. Kime.
2. Non-surgical Treatment of Hyperthyroidism. M. C. Sexton.
3. When Did Disease Begin? J. N. Hurty.

2. Non-surgical Treatment of Hyperthyroidism.—M. C. Sexton cites two cases in which treatment was directed toward both the thyroid and the gastrointestinal tract. The drug used is the yellow or protiodide of mercury, which is administered in $\frac{1}{4}$ gr. doses, three times a day. The patient is also given complete rest in bed and is placed upon a light diet consisting chiefly of milk. The proteins are restricted to one piece of lean meat a day, and the patient is encouraged to drink plenty of water. After the bowels have been thoroughly cleaned out with saline cathartics, alkalies are administered in the form of bicarbonate of soda and lithia waters until the urine is distinctly neutral to litmus. Insomnia is treated by doses of one of the bromides or chloral hydrate per rectum. If improvement follows the patient is allowed up after ten days, the diet is increased, but the patient continues the use of the protiodide as before.

Le Progrès Médical.

January 15, 1921, xlix, 3.

Epidemic Hiccough.—Blum of the Strasburg faculty reports seven personal cases of this malady and sums up the latter in ten dicta, as follows: The hiccough always appeared abruptly after the patient had developed a common cold, and never lasted over a few days; its appearance corresponded with anorexia, coated tongue, eructations, and at times emesis; radioscopic had always shown an air pocket in the stomach and some interference with the play of the diaphragm; mostly there was tracheobronchitis as well as rhinopharyngitis; the cough might precipitate the hiccough or the converse could occur; fever never went above 38° save in one patient who had angina; there was no other phenomenon at any time which could be called nervous save slight and transitory headache; the disappearance of the hiccough was distinctly connected with the disappearance of the gastric symptoms; the author's patients were all males; hiccough was never seen in connection with other diseases than those above mentioned. Most of the subjects showed an asthenia comparable with that in the course of influenza. The author discusses theoretically the part played by the prolonged warfare on the atmosphere, which was filled with foreign matter in very fine subdivisions and which he thinks may have been an important factor in lowering the resistance of the lungs. This might explain the pandemic of 1918, and the author regards the epidemic of hiccough as due to the same factor. Since the hiccough appears to be due to gastric disturbance purely, he is inclined to accuse swallowed air.

Book Reviews.

DIE PATHOLOGISCHE BIOLOGIE (IMMUNITÄTSWISSENSCHAFT). Eine kurzgefasste Uebersicht über die biologischen Heil und Erkenntnisverfahren für Aerzte und Studierende. Von Professor Dr. HANS MUCH, Direktor des Universitätsinstituts für Immunitätswissenschaft und des Tuberkuloseforschungsinstituts in Hamburg. Dritte Auflage. Leipzig: Curt Kabitzsch, 1920.

THE third edition of this work appears six years after the second and has undergone quite radical changes. Since the appearance of the second edition Much has developed his theory of partial antigens and his belief in the truth of this theory runs like a thread through the entire book. The experimental evidence upon which this theory is based is not presented, but from what he says about it the possibility of some confusion of hypersensitiveness reactions and true antigen-antibody reactions is apparent. Immunologists generally are not yet prepared to accept the dictum that lipoids and neutral fats may produce antibodies, and in the absence of generous experimental evidence it is necessary to withhold an opinion on the question. The text throughout is brief and is characterized by the epigrammatic style which Much affects. There is at least one serious omission, his neglect to mention toxin-antitoxin injections in the prevention of diphtheria. His discussion of the Abderhalden and Wassermann reactions is good, but the presentation of the technique of these and other tests is so brief as to be almost valueless. The book has many points of interest, but will hardly prove an essential one to American immunologists.

PRÄTIKUM DER KLINISCHEN CHEMISCHEN, MIKROSCOPISCHEN, UND BAKTERIOLOGISCHEN UNTERSUCHUNGSMETHODEN. Von Dr. M. KLOPFSTOCK, San-Rat und Dr. A. KOWARSKY in Berlin. Sechste Auflage. Berlin und Wien: Urban & Schwarzenberg, 1920.

THIS is a much larger volume than the third edition, which was the last previous one to reach this country. Much of the added material is naturally that developed as a result of the lessons learned during the war, but the endeavor has been made to bring the subject up to date in all respects. This effort has not been wholly successful, for the authors have apparently not been familiar with the development that has taken place, especially in this country, in methods for chemical examination, especially of the blood. There is other ample evidence that they have not had access to our medical literature during the past five years or else have not chosen to notice it. The work is comprehensive, but is of but limited practical value in this country.

HISTORY AND BIBLIOGRAPHY OF ANATOMIC ILLUSTRATION. In Its Relation to Anatomic Science and the Graphic Arts. By LUDWIG CHOLANT, translated and edited, with notes and a biography by MORTIMER FRANK, B.S., M.D., Secretary, the Society of Medical History, Chicago; Attending Ophthalmologist, Michael Reese Hospital, Chicago. With a biographical sketch of the translator and two additional sections by FIELDING H. GARRISON, M.D., and EDWARD C. STREETER, M.D. Chicago, Ill.: The University of Chicago Press.

THE classical work of Choulant, "Geschichte und Bibliographie der anatomischen Abbildung," published in Leipzig in 1852 has been so long out of print that its very existence was unknown to any but anatomists and students of the history of medicine, and even those who had access to the work in public or private libraries found the task of deciphering the antiquated, lumbering German text in which it was written too formidable, and contented themselves for the most part with looking at the quaint illustrations. But there was a great deal of meat hidden in the book, as this translation shows us, and the medical and artistic public owe a debt of gratitude to the late Dr. Frank for the gift he brought them in this English version. The English edition is a vast improvement on the original German one, for the translator simplified the language, so that the reading of the book, originally so toilsome, has now been made easy and pleasurable in its English dress. The work is also larger than the origi-

nal, being supplemented by notes made by Choulant, probably in anticipation of a revised edition, and enriched by additions written by the translator and by Dr. Fielding H. Garrison and Edmund C. Streeter. Before the work could be published Dr. Frank was called by death, and the many friends whom his untimely taking away had bereaved determined to publish the volume as a fitting memorial to their late associate. The book is handsomely printed in the best style of the University of Chicago Press, and is an invaluable contribution to the growing literature of the history of medicine. It emphasizes the irreparable loss to the same science in the premature death of its translator.

THE AFTER-TREATMENT OF SURGICAL PATIENTS. By WILLARD BARTLETT, A.M., M.D., F.A.C.S., and Collaborators. Two volumes. St. Louis: C. V. Mosby Company, 1920.

THERE are many good books on the after-treatment of surgical patients, but this work by Bartlett and a considerable number of collaborators is by far the most pretentious and best that we have seen and covers much more ground than the bare title indicates. The work is divided into two volumes, the first of which deals with general subjects, such as the ideal postoperative room, anesthesia, artificial feeding, wound treatment, bandaging, exercises and massage, hydro-, x-ray, and radium therapy, special symptoms and conditions such as headache, hiccough, shock, hemorrhage, postoperative ileus, acute dilatation of the stomach, fat embolism, postoperative psychoses, hemophilia, thrombophlebitis, postoperative pneumonia, and numerous others. The second volume deals with the measures in after-treatment as they are applied following operations in various regions and upon various organs. Bartlett has been assisted by quite a corps of collaborators, many of whom are specialists who have covered the after-treatment as applied to cases in their particular field.

This work should be of great service, not only to members of house staffs but to experienced surgeons as well, not one of whom can fail to find many suggestions for the better treatment of his cases. The work should be of especial value to the occasional operator and those who by force of circumstances operate only in emergencies; for these men usually operate in sanatoria and private houses and have seldom had sufficient hospital training to have developed adequate rules for postoperative care.

GRUNDRISS DER PSYCHOLOGIE. By Prof. CARL OPPENHEIMER and Prof. Dr. OTTO WEISS. Volume I, BIOCHEMIE. Leipzig: Georg Thieme, 1920.

DR. OPPENHEIMER'S work is a complete biochemical analysis of the human body and its functionings. The chemical composition of all body material is given in a clear and concise way, yet the book strikes the reader by its thoroughness. The chemical and bacterial action of the ferments is well given. The chapters on metabolism, while not detailed, are extremely complete. There are some pages on the regulation of body functions by the liver and the glands of internal secretion. The book is highly recommended as a hand reference book for medical students and laboratory workers.

AIDS TO OSTEOLOGY. By PHILIP TURNER, B.Sc., M.B., M.S. (Lond.), F.R.C.S.; Assistant Surgeon, Guy's Hospital; Teacher of Operative Surgery in the Medical School. Second edition. New York: William Wood & Co., 1920.

THIS pocket volume contains, in condensed form, the anatomy of the bones. Though small in size, there is a large amount of information packed into the book, and it probably contains as many details as are to be found in such standard works as those of Gray or Cunningham. There are no illustrations, and the condensed style makes the book rather difficult reading. For the beginner in anatomy, the easier plan would be to study the bones from some large (and illustrated) textbook, and then to use this little volume for purposes of review. The book differs very little from the former edition, but there is less change to be expected in a book on osteology than in any other book used by the medical student.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held February 3, 1921.

THE PRESIDENT, DR. GEORGE DAVID STEWART, IN THE CHAIR.

Measles Experimentally Produced.—Dr. FRANCIS G. BLAKE presented this paper in which he said that it was a familiar fact that measles occupied a prominent position among the acute infectious diseases that led to severe and often fatal diseases of the respiratory tract. This was particularly true of children under five years of age and of children in institutions. Strict quarantine had been largely inadequate because measles was most contagious during the prodromal stage. That the disease might be prevented by prophylactic inoculation was by no means a new idea. Many such attempts had been made by cultural studies and animal inoculation. The former method had not up to the present time yielded positive results, and whether the disease could be communicated to animals was still an open question. The present study was undertaken to determine whether more evidence might not be brought to show whether animals were susceptible to inoculation with the virus of measles. Inasmuch as the virus in a human being infected with measles was present in the secretions of the respiratory tract and the mucous membranes of the respiratory tract were the path of entry for the infection, the method employed was to inoculate monkeys with nasopharyngeal washings collected by saline irrigation of the nasopharynx, using 5 to 10 c.c. of the nasal washings inoculated intratracheally. This method was open to the objection that other organisms besides the virus of measles were present in the washings and were injected into the trachea, but he believed these organisms were mostly saprophytes which were readily disposed of by the mucous membrane. To overcome this objection the washings were subsequently filtered and the filtrate injected and the blood from infected monkeys shown to be free from other organisms was also used. The attempt was made to transmit measles to 12 monkeys. Of these 10 after five or six days came down with the group of symptoms characteristic of measles. One monkey died of an intercurrent pneumonic infection and another failed to show evidence of infection. Seven were inoculated with unfiltered washings and three with washings passed through a Berkefeld filter. Several control monkeys were inoculated with filtered and unfiltered washings not containing measles virus, and none of these animals showed any evidence of measles infection. The symptomatology induced in the monkeys by the inoculations of washings containing the measles virus consisted in listlessness, drowsiness, loss of appetite, and a diminution of the leucocyte count; the conjunctive became inflamed, and small discrete, hyperemic macules appeared over the lips and inside of the cheeks. One to five days after the onset a red maculopapular rash appeared, usually coming out first on the face, and spreading to the chest, abdomen, and inner side of the thighs. The exanthema reached its height in three or four days and then faded. The acute catarrhal inflammation persisted throughout the infection. The exanthem in the mouth began with the onset of symptoms or within twenty-four hours afterward. These were typical Koplik spots. These spots were few at first and might pursue one of two courses; they might either disappear or a confluent rash might develop. The incubation period was quite uniform, being from six to ten days. The rash went through the regressive stages characteristic of measles in the human being, going on to desquamation; it was rarely as thick or widespread as measles rash in man. The fever might go up to 105° or 106° F. or the animal might go through the disease with little or no fever, or again the fever might be present only in the prodromal stage before the appearance of the exanthema. The white blood counts showed a constant diminution below the normal. This began before the symptoms were recognized and continued for several days, the leucopenia being sometimes as low as 4,000 for several days. In only one respect had the reaction differed from the

course of measles in man and that was that none of these monkeys had exhibited any evidence of rhinitis or bronchitis. The regularity with which this group of symptoms developed and its close resemblance to measles in man were presumptive evidence that the symptoms were due to the virus of measles and not to the ordinary organisms present in the mouth. Furthermore it had been shown that the reaction occurred when monkeys were inoculated with filtered washings containing none of the ordinary mouth flora. The possibility that the reaction might be due to some filterable toxic substance rather than to the living virus of measles suggested itself, but such possibility had been excluded by the successful transmission from monkey to monkey. The reaction had also been successfully transmitted by tissue emulsion and by blood through a considerable series of animals. Dr. Blake described experiments which indicated that the blood was not infectious during the early part of the incubation period. Experiments were carried out with the blood through twelve successive passages. During these experiments it was shown that as small an amount as 1 c.c. of blood was infectious when injected subcutaneously and also when injected intravenously. The infective virus was shown to be present in the plasma and not in the blood cells. Other experiments indicated that one attack conferred immunity against subsequent infection and that this immunity was effective against heterogeneous as well as homologous virus. Finally histological studies were made of the lesions in the skin and mucous membranes. Tissue consisting of small pieces of skin and mucous membrane, excised under anesthesia, and skin and mucous membrane from monkeys killed after transmission, were studied microscopically. The slides shown demonstrated a multiplication of endothelial leucocytes and moderate exudate about the capillaries in the corium. The greatest cellular reaction was that of the endothelial leucocytes. The leucocytes showed occasional mitotic figures. The lesions were in the upper part of the corium close to the epidermis, hair sheaths, and sebaceous glands. The lesions in the epidermis were in the Malpighian layer which showed minute foci of serous exudate, vacuolation of epithelial cells, and infiltration with large mononuclears. Minute vesicles developed in the cornified layer. The slides illustrated three stages in the development of the Koplik spots. The skin and mucous membrane lesions of measles had been well described by Ewing and Mallory, and Mallory had expressed the opinion that the lesion in the monkey was essentially the same as that in man. The conclusion was therefore warranted that the monkey was susceptible to measles and that the reaction produced in monkeys might with justification be called experimental measles.

Dr. JAMES EWING said that in accepting the Chairman's invitation to discuss Dr. Blake's paper he wished to make it clear that he was conscious of no particular qualifications which fitted him to discuss the paper, although he confessed to a long interest in this disease which once led him to spend considerable time in a careful histological study of the lesions of measles. He had enjoyed Dr. Blake's description of the careful, logical, and systematic experiments which seemed to him model of precision and accuracy, and for which reason the results were not a matter of chance but a certainty. If heretofore any one had doubted the possibility of the transmission of measles to monkeys he would not leave the hall with any further doubt. Dr. Blake and his associates were to be congratulated on the type of work and on their results. There was little to be said except to express the hope that they would continue their experiments. He thought it would be interesting if Dr. Blake would discuss the characteristics of the pneumonia observed in these animals and compare it with the types of pneumonia following measles which they had seen in the army. He would like to know whether Dr. Blake had made any histological studies on the animals dying of bronchopneumonia. With regard to the lesions of the skin he had spoken of the proliferating endothelial cells about the capillaries. Dr. Ewing said he had spent many hours trying to find a specific structure, possibly a pathogenic protozoan. In this he had been unsuccessful though he had found a number of other interesting things in the

endothelium and epithelium. It would be interesting to know whether Dr. Blake had observed any bodies in the stratified epithelium that might be lined up with those observed by Dr. Wolbach in typhus. We needed no new experimental evidence to show that measles could be transferred from one individual to another. The work of Hektoen in 1905 had demonstrated this. Since the time of Horne in 1770 many had used inoculation as a preventive against the disease. Then more recently Anderson and Goldberger had shown that measles could be transferred to animals. However, he had no criticism but only admiration for the work presented, since it was more detailed and convincing than any previous study. But satisfactory and convincing as this study was, he would like to point out a further duty for Dr. Blake and his coworkers in the attempt to make the work of practical benefit. One characteristic of modern science was that it did not concern itself sufficiently with practical results. Jenner's work was not conducted in a way that we to-day would consider strictly scientific, yet he was successful in transforming smallpox from a lion into a cat, though its cause was still undiscovered. So while we knew a great deal about measles, the first step was to find how by harmless inoculation the disease could be prevented. No doubt that was the reason Dr. Blake had taken up this work as a preliminary step. It was a matter of congratulation that the work was being done by a man as competent as the report had shown Dr. Blake to be.

Dr. LOUIS I. HARRIS said that when he heard Dr. Ewing confess himself rather nonplussed to find something to add to Dr. Blake's presentation, it was a relief to him as he felt utterly unprepared to discuss the paper from the standpoint of the laboratory worker. He took it that his presence here was testimony to the fact that it was desired to make this work not merely of academic value, but a study that would have a practical application to the problems of those who were endeavoring to cut down the mortality from measles and the complications that followed this disease. The facts regarding measles were no doubt familiar to all present, but it might perhaps be well to recall them. Measles was often regarded by physicians as an extremely trivial disease, but it was not so trivial when one escaped from the provincial standpoint which was inevitable if one was guided by personal experience alone. During the twelve year period, from 1900 to 1911, in twenty-two countries 32,000,000 cases of measles were reported, with 366,000 deaths attributed to measles. It must be remembered that many cases of measles were not reported and that many deaths due indirectly to measles had not been recorded as due to this cause. In New York City, where for the past twenty years we had had fairly reliable statistics, there had been 547,482 cases of measles reported to the Department of Health, on an average of 27,374 annually. The total number of deaths from measles was 13,651. There was, however, no record as to the number of cases in which death was attributed to other causes, but in which measles was the direct or indirect cause. The average number of deaths annually reported was 683, or about 1 per cent. of all deaths was attributable to measles. It would be extremely valuable to discover by some means how many deaths from bronchopneumonia and other diseases which were directly due to measles were missed in this statistical summary as a result of incomplete statement of cause of death on death certificates. This work of Dr. Blake's brought us one step nearer the goal of prevention and control such as we reached in the case of smallpox long ago. The problem was one that concerned particularly the children of preschool age—those under five years. It had been found that in communities in which measles was prevalent that 93 per cent. of all cases occurred in children under five years of age. It was an important problem, not only in so far as it concerned measles but in relation to tuberculosis as well. The statement had been made that measles was a direct cause of tuberculosis. If it were it was highly important that opportunity should be given to drive home that fact by experimental and other demonstration. It was well known that in the army measles created havoc by causing a predisposition to infection by the *Streptococcus hemolyticus*. Had it not been for the sequence of measles, the streptococcal infection, and finally pandemic "influenza,"

there might not have been such a serious tale to tell. At all events it seemed evident that measles bore a direct relation to the high mortality that ensued in the influenza pandemic. This was especially evident at Camp Beauregard where there were large numbers of men from rural communities who had not had measles and who therefore offered a large amount of susceptible material. Among these, the mortality and morbidity from measles were extremely high, it being estimated that measles contributed 31 per cent. of the deaths. The complications due to the *S. hemolyticus* was the most potent cause of fatal sequelæ. Measles was equally important in industrial camps. Dr. Harris referred to various attempts that had been made to vaccinate against measles, and stated that the public health workers were watching for something to take the place of bungling and contrary methods for the control of measles that were now prevalent throughout civilized countries. In one country there was no provision at all for dealing with measles in another a bonus, or money premium, was placed on the reporting of measles. It would seem that the Hippocratic oath and the ethical traditions of the medical profession should make unnecessary the giving of a bonus for the reporting of disease. In many countries the enforcement of the law requiring the reporting of measles, as indeed the public health measures employed for its control, were ineffective. It seemed that all these facts argued for the continuance of such methods of research as had been presented this evening, in the hope that some method of dealing with measles comparable to the Schick test and active immunization in diphtheria might be discovered which could be applied before exposure to measles, and which would prevent the disease or delay it until that age at which it produced little or no disastrous effects.

Dr. WILLIAM P. NORTHRUP said he could truthfully say that he had not expected to discuss this subject, but he would not do justice to his feelings if he did not express his appreciation of the paper of the evening. He did not think it necessary to argue for the importance of measles. At the Foundling Hospital they had always been punished with measles in fearful epidemics, and that institution was no exception. If there was anything that would make a sister of charity turn pale it was to hear the doctor say "measles." If there was an epidemic in any institution it was something fearful. The same was true of camps and jails and in public institutions of all kinds. It was one of the worst things that could happen. In the Foundling Hospital they had been able to control diphtheria and smallpox, but when it came to measles they were helpless. He was accustomed to think that there were two diseases that children had that should be watched very closely—measles and whooping cough. After a child had had measles one should always ask whether it had made a good recovery, and ascertain some of the details in reference to recovery, as how long the child had been in bed and how quickly it made a good recovery after measles. The same was true of whooping cough. It was a fearful thing not only in its immediate effects but in the possibility of tuberculosis, particularly in those glands at the bifurcation of the trachea and at the root of the lung. The complications and sequelæ of measles and whooping cough were worse than those of scarlet fever or of any other disease. Dr. Blake spoke of the monkey having no rhinitis. He thought that was rather peculiar. There was an eruption of the mucous membranes and of the cutaneous surface, on every part of the mucocutaneous surfaces in contact with the atmosphere. He did not see how the monkeys escaped the rhinitis unless it was that the monkey's nose had a good vent and did not show the rhinitis. Dr. Northrup said that in a long time he had not heard such a beautiful paper, one possessing such logical perfection, such dignity, such beautiful simplicity. He wished all students could hear it for those beautiful qualities and also for its summary and ending, and the dignity and clearness with which it was delivered.

Dr. RUFUS COLE stated that he had had nothing to do with Dr. Blake's work but to be interested in it and to support it. His great interest in measles had been aroused by his experience in Southern camps where he discovered for the first time what a dreadful disease it was when complicated by streptococcus pneumonia,

It was the worst experience he had ever had although he had had some experience with smallpox, so it seemed to him that measles was an extremely important disease to be studied in the Hospital of The Rockefeller Institute. Dr. Blake's experience had been similar to his and he had come back to the Rockefeller Institute to undertake these studies, the results of which he had presented. Both Dr. Blake and Dr. Cole, being clinicians, were naturally much interested in the practical aspects of the question but he felt that little could be accomplished in a purely empirical manner and that first it was necessary to obtain scientific experimental evidence upon which to base practical preventive measures. He hoped that with the results already obtained Dr. Blake could now proceed to the practical applications of his work and that later he could report upon the results of these endeavors.

Dr. WARFIELD T. LONGCOPE said that he felt very much as the other speakers had expressed themselves, that one might go on speaking indefinitely with admiration but it was quite impossible to discuss a paper so logical in its sequence and so convincing. Dr. Ewing and others had mentioned that the disease had previously been transmitted to animals and many had attempted to transmit it without success. The thing Dr. Blake had done was a perfectly original piece of research. He had attacked the problem from a new standpoint and by new methods and had obtained entirely new results. He had developed a method by which this disease or virus could be cultivated in animals in a definite way which brought similar results to those reached in bacterial diseases studied in a similar way. This piece of work constituted a wonderful basis from which to proceed further. One need not suggest the important possibilities which were obvious to all. He supposed Dr. Blake had gone ten years ahead of other investigators in devising methods of inoculation.

Dr. CHARLES HERRMAN said he agreed that this piece of work was the most thorough that had been done on this subject. It was much more complete and the number of animals was larger. The results agreed in the main with those of Anderson and Goldberger but their work was not so extensive and this work was very much more conclusive. The negative results obtained by some investigators were due to the fact that they did not use active material for inoculation, or the material was not obtained at the right time, or the subject of the experiment was already immune to measles. Frequently an individual had had a milk attack of measles when there was no statement in his history showing that he had had measles. It was well known that an individual might have measles in such a mild form that the disease could not be recognized unless there was another case of measles in the same family. As the infecting agent was present in the filtrate, it was improbable that the diplococcus isolated by Tunncliffe was the cause of the disease. Dr. Herrman stated that he was interested in the question from the practical side. A method of immunization to be of practical value must be similar to that used in immunization against smallpox and must be one that could be used early in life. His method was crude, but it had yielded some rather convincing results. Since practically all mothers in New York City had had measles, all children under five months of age were relatively immune; those under two months were absolutely immune, those between two and five months were relatively immune. The easiest method of inoculation was by the way the disease was usually transmitted, that was from mucous membrane to mucous membrane. All that was necessary was to take some of the secretion of the nasal mucosa from a measles patient just before or just after the appearance of the eruption, and transfer it to the nasal mucous membrane of the susceptible animal or human being. Three per cent. of all individuals were naturally immune, otherwise the disease was transferable, and a relative immunity in infants from three to five months might be changed from a temporary to a permanent immunity. If the immunity thus conferred lasted only a few years a great deal would be gained because practically all the deaths in measles, due chiefly to bronchopneumonia, occurred in children under five years of age. Dr. Herrman stated that he had carried out this method in 150 infants, but, as all knew, it was extremely difficult to follow up a large number of infants

over a long period of time. He had begun the inoculations five or six years ago. While in the service follow-up work had to be discontinued. However, he had been able to follow up 25 children who had been inoculated and subsequently exposed to measles. Of these 25 children only two contracted measles. When one considered that ordinarily 95 to 97 per cent. of all infants and children who had not had the disease became infected when exposed, it seemed that it was perfectly possible to immunize. There were two points, however, that must be observed. The material used for inoculation must be bacteria free and some method must be devised by which the material could be preserved. Dr. Herrman expressed the belief that it was perfectly possible to immunize against measles as we immunized against smallpox.

Dr. BLAKE, in closing the discussion, said that only one of the monkeys had died of bronchopneumonia. Dr. Ewing had asked if he had looked for the Wolbach foreign bodies. He had used appropriate stains on a large number of sections but had been unable to see any of these bodies. Dr. Harris had emphasized the importance and seriousness of measles as a public health question. He could add an instance showing the popular recognition of this fact. A woman in New Rochelle was very much exercised because there were two or three cases of smallpox in that locality and wondered whether she should have her children vaccinated. She finally said that she did not know that it was necessary to have the children vaccinated because smallpox did not mean anything compared with measles.

Stated Meeting, Held February 17, 1921.

THE PRESIDENT, DR. GEORGE DAVID STEWART, IN THE CHAIR.

The Typhoid Carrier, from the Laboratory, Medical, and Surgical Standpoints.—Dr. ABRAHAM L. GARBAT made this presentation, which consisted in an abstract of a monograph which had been awarded the Cartwright prize by Columbia University, describing research work carried out in the course of a waterborne typhoid fever epidemic. This epidemic occurred in an internment camp at Hot Springs, N. C., in August, 1918, and in the course of the epidemic 183 patients were transferred to U. S. General Hospital, No. 12 at Biltmore, where the study was carried out. The study of the cases did not terminate with the cessation of acute manifestations but was continued during convalescence. The observations were made by the same laboratory worker and by the same technique in all instances. The fact that the death rate in some epidemics of typhoid fever was as high at 58.4 per 100,000 and that there were annually in the United States about 150,000 deaths from typhoid fever made it of great importance to detect typhoid carriers. An article published by the speaker in 1916 dealt with the value of duodenal cultures as a means of determining convalescence from typhoid fever and gave the results of a study of 12 cases in which typhoid bacilli were demonstrated in the bile and not in the feces. The present study was undertaken on a much larger scale. Bile cultures were made in 136 convalescent typhoid fever patients, the bile being collected by means of the duodenal tube. The tube was given at night and the following morning the bile was aspirated. It was found that large amounts of bile could be aspirated from the fasting stomach. The statement had been made that one very rarely obtained much bile from the fasting stomach. That was incorrect; the amount was very variable; one might get up to 80 c.c. or as small a quantity as 1 c.c. The bile in almost all these cases was thick and turbid and contained mucus. In only one instance were there active motile typhoid bacilli in the hanging drop. They used the Endo media and the examinations were made by standard technique. The first question taken up was whether the repeated examination of the feces was a fair index as to the presence or absence of typhoid bacilli in the intestinal tract. In making these examinations he had applied the Army rule, and found that 11 per cent. of the typhoid patients who were usually considered ready to leave the hospital and mingle with other people might still be discharging

typhoid bacilli undetected by the general stool examination. Of these 136 patients 15 continued to excrete typhoid bacilli for sixty-eight days. In this city in 1900 the Sanitary Code permitted the discharge of typhoid patients when two specimens of feces at an interval of twenty-four hours were found to be free from typhoid bacilli. In other words, by the routine stool examination many typhoid carriers were missed. The second question considered was whether it was possible that typhoid bacilli were destroyed on their way down from the gallbladder, as noted in cases with a negative stool culture and a positive bile culture. It was found that the longer typhoid bacilli persisted in the bile the more likely were they to be found in the stools. In the early days of convalescence bacilli might not be detected in the stools at once, but only after numerous cultures.

One could not tell from a negative stool in the early days of convalescence which ones would show typhoid bacilli later. A third question was whether in cases with positive duodenal cultures the typhoid bacilli were constantly present in the bile or whether there were intermissions when none could be found. Specimens of bile were taken every two hours for twenty-four hours, and after each specimen was collected the tube was washed with sterile water. It was found the bacilli were constantly present. Repeated cultures were made over long periods of time and it was found that the cultures were either constantly positive or if they became negative they remained so, but they might be absent from the feces for months and then recur. The writer was convinced that this intermittency in the stools was only an apparent one. There were rare exceptions to the constancy of the bacilli in the bile, but in such instances the absence of the bacilli from the bile did not continue long. In one case of cholelithiasis there was an occasional negative culture and in this instance cholecystectomy failed to cure the carrier state. The author required two consecutive negative bile cultures at intervals of two days to establish freedom of the bile from bacteria. A fourth question investigated was whether the bile cultures were accurate in detecting carriers, whether they were more accurate than the stools and whether the stool examinations should be discarded. This brought up the question as to whether there was such a thing as an intestinal carrier where the bacilli were lodged in the intestines. In the entire series of 164 cases he had been able to find only one such patient. True intestinal carriers constituted about 0.6 per cent. of all carriers. However, it was not safe to omit stool examinations entirely. The speaker made it a practice to examine two stools at intervals of six days. Every typhoid patient who continued to show typhoid bacilli in the urine or stools after the acute stage should be classed as a carrier. Temporary carriers were usually only such for weeks or months, and then cleared up. Every carrier should be considered a permanent carrier until proved otherwise. It was found that those patients who showed typhoid bacilli longer than five or six months usually became chronic or permanent carriers. Of 164 cases, 53, or 32 per cent., continued as feces carriers after the temperature reached normal; 46 cleared up in from one to four months; the remaining seven would probably be permanent carriers. This was about 4 per cent. of all typhoid fever cases. Bile carriers were classified into three types, gallbladder, liver, and duct carriers. No evidence had been obtained that there were pancreatic carriers. It was possible to differentiate between the intestinal and the gallbladder and liver carriers in the early period of convalescence. The intestinal carrier began to show bacilli early and in great numbers and in pure culture; on the other hand, when the bacilli came from the bile they were present in the feces in smaller numbers and with greater irregularity. A fifth question which Dr. Garbat had studied was that of differentiating the different types of bile carriers. This they had not done with any regularity. The idea had suggested itself that symptoms referable to the gallbladder might be of some aid. Two of the patients in this series had manifested symptoms referable to the gallbladder during convalescence. In one of these bacilli were found in the gallbladder, but not in the other. In one case showing a positive bile culture, after cholecystectomy the bile still continued to show the typhoid bacilli. In this case it was found

that a large stone was fixed in the cystic duct and the seat of the infection was the liver. In another case the bacilli were found in the bile or both the liver and the gallbladder. In the liver carriers he could not say whether the bacilli were in the liver tissue or in the hepatic ducts. As to the way in which the bacilli reached the gallbladder, they were probably carried by the blood to the liver and then into the bile, and at times into the gallbladder wall. Another route of infection, the ascending, might be by way of the common bile duct. This mode of infection was probably not frequent but it was a possibility. A sixth question was whether there was any factor predisposing to the carrier state. Were there any indications as to which patients might become carriers? No light had been thrown on this question by a study of the blood cultures. The majority of carriers seemed to have had a longer illness than other typhoid fever patients. Here, however, the protracted illness was probably not the cause of the carrier state, but more likely was caused by the persistence of the bacilli in the body. All medical treatment of typhoid carriers had been ineffective. When they studied this series of cases with relation to cholecystitis, it was found that 8 had definite evidence of cholecystitis. This relation was important with reference to the operation of cholecystectomy in gallbladder carriers. Once the symptoms of cholecystitis became evident in a typhoid patient operation was warranted earlier than otherwise. Occasionally a cholecystectomy done years after an attack of typhoid fever revealed the fact that the patient had been a gallbladder carrier for all those years. If operation was delayed too long in typhoid gallbladder carriers surgical interference became more difficult and dangerous. Not all persons who became gallbladder carriers manifested symptoms referable to the gallbladder during the disease. Cholecystectomy might in some instances be a cure for the carrier state but the results were not uniformly successful, and the cause was evident when one kept the classification of bile carriers in mind. Only the gallbladder type of carrier was amenable to operation. Unfortunately it was not always possible to differentiate between gallbladder and liver carriers hence cholecystectomy plus prolonged drainage was necessary, together with continued examination of the discharge. If repeated examination of the discharge showed the absence of the typhoid bacilli the wound might be closed, but if they were present drainage should be prolonged and in this way in a number of instances the infection could be cleared up. If a bile carrier had not cleared up after six or eight months a cholecystectomy should be performed, and in cases in which there had been symptoms referable to the gallbladder, operation might be undertaken earlier. A study of urine carriers had also been undertaken and 2500 cultures of urines from the 164 patients made. Every convalescent typhoid fever patient was given three urine examinations at intervals of six days. The patients were found to divide themselves into three groups (1) those in which the typhoid bacilli were at no time present in the urine; (2) those in which the urine was at first constantly positive and remained so for a shorter or longer time, and (3) those in which the urine was sometimes positive and sometimes negative. It was this group that was studied in detail. The first question investigated was whether the time of voiding made any difference. They selected 12 patients, and every specimen was collected separately and cultured separately. As a result he had found that the hour bore no relation to the presence or absence of the bacilli. The specimens might change from positive to negative and vice versa every few hours. They then extended the study over weeks, counting the bacilli, and found a marked intermittency even with hourly voiding. The high counts obtained in some specimens seemed to be accounted for by the growth of the bacteria in the bladder. All their experience tended to prove that culturing single specimens of urine and concluding from a negative result that bacilli did not exist in the urine was erroneous. Three negative cultures was not a dependable rule if complete freedom from bacteria was sought. All their observations left no doubt that accurate results were possible only when twenty-four hour specimens were examined. If the examination were made in this manner one or two examinations would be sufficient and a six day interval

between examinations would not be required. Of the 164 patients, 49 per cent. showed bacilluria at some time during convalescence; this was a much higher percentage than was usually given. Of 127 cases examined in the first week after the temperature reached normal 63 per cent. showed bacilluria. An attempt had been made to investigate the pathology of bacilluria in general but only one explanation was found to account for the source of typhoid bacilluria. It seemed, however, that in the majority of cases the bacilli came from the urinary tract above the bladder. Several types of kidney lesions had been demonstrated in urine carriers, such as multiple focal abscess, hydronephrosis, and acute nephritis. Typhoid infection might result in acute nephritis, but a transient bacilluria could not be explained on this ground. Dr. Garbat discussed at some length theories to account for the presence of typhoid bacilli in the urine and bladder. When there was an infection of the kidney the numerous calyces of the pelvis bore the same relation to the kidney as the gallbladder did to the liver, and the intermittency of the bacilluria might in some cases, at least, be explained by the fact that the calyces were flushed out at different times. Urine carriers might be classified along the same lines as bile carriers into urinary, pelvic, and bladder carriers.

Dr. HANS ZINSSER said that he had listened to Dr. Garbat's paper with a great deal of pleasure and regarded it as a finished piece of work. As a bacteriologist, he could express only admiration for the manner in which it had been done. Since water and food sanitation had reached degrees of perfection that made extensive water-borne and food-borne typhoid epidemics a matter of increasingly infrequent occurrence, the sanitary efforts in typhoid must center upon the direct and indirect contact infections from carriers, a problem which was still to be solved. As to Dr. Garbat's percentage of chronic carriers, it corresponded with the figures generally accepted, 4 to 5 per cent. of those convalescing from typhoid. As to the duodenal tube results, Dr. Garbat's work seemed to be much more favorable than that of others who had worked with the tube. As a rule, the percentage of positive findings in the duodenal contents had not been as great as those of Dr. Garbat, though one would expect the percentage in the duodenal contents to be higher in carriers than the stool findings, because of the greater relative purity of the cultures in this material. He thought that the comparison of stool cultures and duodenal cultures, as made by Dr. Garbat, who worked only with the Endo medium, could not be regarded as conclusive, since, in his experience and in that of assistants in his laboratory, a considerably higher percentage of positive stool findings could be obtained by proper use of brilliant green media, such as that described by Krumwiede. An important result of Dr. Garbat's work was the proof of the existence of a pure intestinal carrier. This class of carrier had been worked upon with some skepticism. Gallbladder, duct and liver carriers had been proven, and so classified before this. A pure intestinal carrier had been suggested by Professor Krause, who believed that it might be associated with chronic ulcerations of the intestine and even with low grade appendicial inflammations. Dr. Zinsser could not remember the name of the German investigator, but called to mind distinctly another pure intestinal carrier proved by methods similar to those of Dr. Garbat in 1916. Dr. Garbat had spoken only of the surgical treatment of carriers. Dr. Zinsser regretted that he had not taken up the medical treatment, as well. He said that the carrier problem was a very difficult and large one in preventive medicine, and it centered about the proper handling of the carrier, a problem in which not only medical but legal problems were involved. Though results of investigation showed that about 5 per cent. of typhoid fever patients become chronic carriers, there were probably a great many who were carriers who had never had typhoid fever in typical form. A great many of those vaccinated against typhoid fever might become carriers with the typical disease, and this, indeed, was the case during the war, when extensive outbreaks of diarrhea and intestinal disease occurred in all the Armies of the Allies, and probably of the Central Powers, as well, during July, August and September of 1918, when it seemed fair to say that pretty nearly four out of five

men had some intestinal upset associated with diarrhea. A considerable percentage of the few of those that were examined had typhoid, paratyphoid, and dysentery bacilli in their stools. It seemed fair to suppose that many of these men had typhoid and paratyphoid infections, rendered atypical by the vaccination immunity, and as more and more people became vaccinated, more and more carriers would develop in whom the warning of their probable carrier state supplied by the history of an attack of typhoid fever, was lacking. Medical treatment which Dr. Garbat did not mention, had, to be sure, offered very little that was hopeful. A great many methods had been tried, and a few of them recently had seemed to give hopeful results. Two German observers had reported within recent years that they had managed to cure a limited number of typhoid carriers by the use of animal charcoal and thionin, and animal charcoal and tincture of iodine. Methylene blue and many other drugs that were eliminated partially through the bile seemed to have failed completely. Vaccination of carriers had been unsuccessful, as, indeed, there was no theoretical ground for hoping that it might prove a cure, since the organisms in the carrier were not physiologically within the body. It was perhaps natural, therefore, in view of the very meager results of medical treatment, that interest should center upon surgical treatment which seemed pretty sure to cure the pure gallbladder carrier. But surgical treatment could not solve the sanitary problem, if one considered the large number of typhoid carriers in any community, removal of gallbladders certainly could not be looked to, except in a very limited percentage of these, and even in the favorable cases it must be left to the surgical judgment of the individual surgeon whether or not the operation could be safely undertaken, for a certain percentage of these cases did not clear up, and there have been a not inconsiderable number of deaths following the operation. The sanitary solution of the typhoid carrier problem would rest primarily upon such careful and rational studies as that of Dr. Garbat. Epidemiological study of the individual typhoid case must make the beginning of preventive organization, backed up by careful carrier examinations of the limited group to which the epidemiological study led. Beyond this, public health measures were only successful when they were based upon feasible procedures. Typhoid carriers should be reported, and there should be systematic carrier examinations of individuals engaged in all occupations associated with food handling. The carrier when found should be reported, registered, and his whereabouts and occupation should be under constant health department supervision. Carriers should not be allowed to follow vocations as cooks, waiters, or similar occupations involving food handling. All this might be expensive, but, from the economic standpoint, it would be cheaper to compensate such people if they were to seek other employment, and to retrain them, than to permit them to continue as food handlers, which might involve great loss to the community. In closing, Dr. Zinsser said that he could not criticize anything in Dr. Garbat's paper. His studies, as well as those of others who had used the duodenal method recently, were important in showing the directions along which rational methods, which would eventually restrict typhoid fever, could be developed. Such studies, coupled with the administrative health board activities outlined above, and constantly increasing generalization of vaccination, with, finally, education of the carrier and the general public in the simple processes of hygiene, as to cleanliness of hands after stools and before taking meals, these were the lines along which the carrier problem would have to be controlled for the present.

Dr. SAMUEL W. LAMBERT said he did not know what a pure clinician could say regarding pure, scientific bacteriological technique presented in such an able way. He had read the paper some months ago and since then had been more careful in analyzing methods to discover carriers. In spite of the problem of the carrier, typhoid fever at least so far as this city was concerned was disappearing. They used to have 20 or 30 cases on the medical service of the Presbyterian Hospital every year; last year they had only six cases. This was the result of vaccination and of the education of the community. We were, of course, all interested in the discovery of carriers and in this the clinician was de-

pendent upon the laboratory. The laboratory must tell the clinician when he could discharge the typhoid patient. He had found the laboratory more prone to turn in a positive urine than a positive stool culture. He had not used the duodenal tube as a routine procedure and doubted if it could be so used. Certainly if German prisoners of war had to be bribed in order to get them to submit to its employment, its applicability to the private hospital patient was probably out of the question, even if it might be possible to apply it to a few others. The question of the typhoid carrier had always brought to his mind another point—namely, that one might catch the typhoid carrier—and it was rather important to catch him, but what were other cooks and food handlers putting into our food? Dr. Garbat had spoken of methylene blue as a medicinal disinfectant which had failed. The idea had occurred to him that if it were possible to feed all food handlers and cooks methylene blue we might not be able to diagnose the typhoid carrier but we might at least find out which ones were cleanly in their habits. Dr. Lambert took exception to Dr. Zinsser's statement that dealing with typhoid carriers was a question for the surgeon of the future; he thought it was a question for the medical men to determine how typhoid carriers could be disinfecting. We did not possess a real disinfectant for the intestinal tract. Dr. Garbat had done a great piece of work and was to be congratulated.

Dr. GARBAT, in reply to a question as to whether he had traced any relationship between bile carriers and urine carriers, said he had gone into that question, but the time had been too short to include that part of his work. He might say, however, that it was a mere coincidence if the same individual was both a bile and a urine carrier. With reference to the question of operation, these patients who were carriers were willing and anxious to be operated upon, in view of the fact that no medical treatment had been found effective in dealing with the carrier state.

Books Received.

THE MEDICAL RECORD is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.

THE OXFORD MEDICINE. Edited by H. A. CHRISTIAN, M.D., and Sir JAS. MACKENZIE, M.D. Vol. III, Diseases of the Digestive System, Kidneys and Ductless Glands. 828 pages with illustrations. Published by Oxford University Press, American Branch, New York.

BAILLIÈRE'S NURSES' COMPLETE MEDICAL DICTIONARY. Edited by CONSTANCE M. DOUTHWAITE. 206 pages. Published by William Wood & Company, New York.

OPTIMISTIC MEDICINE. By A FORMER INSURANCE MAN. 318 pages. Published by F. A. Davis Company, Philadelphia.

TRANSACTIONS OF THE AMERICAN PEDIATRIC SOCIETY. Edited by OSCAR M. SCHLOSS, M. D. 32d Session, 1920. 353 pages with illustration.

THE SEX-COMPLEX. By W. BLAIR BELL, M. D. 251 pages with illustrations. Published by William Wood & Company, New York.

THE DISEASES OF THE NEWBORN. By Dr. AUGUST RITTER VON REUSS. 626 pages with 90 illustrations. Published by William Wood & Company, New York.

EPIDEMIC RESPIRATORY DISEASE. By EUGENE L. OPIE, M. D., FRANCIS G. BLAKE, M. D., JAMES C. SMALL, M. D., and THOMAS M. RIVERS, M. D. 402 pages with illustrations. Published by C. V. Mosby Company, St. Louis.

Miscellany.

MAN AND DEVONIAN MOLLUSK*.

By F. CAUTHORN, A.M., M.D.,

SUPERIOR, ARIZ.

Man:

Strange inhabitant of the rocky mountain side!
Thrice an hundred miles from where the ocean,
At its nearest point, washes the sand-strewn beach

Or, with relentless lashings, beats against the cliffs,

I found thee.

Thy graceful fluted edge and rounded hinge,
Thy shape entire,

So like the forms now living in the ocean shoals
Bespeak thy kinship and thy former home.

What changes hast thou seen in this old Earth

As æons rolled!

Age begets wisdom,

And with bowed head and humble mind,

I would of thee a lesson and a moral learn.

Mollusk:

Poor fellow mortal!—

Nay, do not wince that such I call thee;

For surely, as the ages roll,

There's kinship 'tween thee and me.

Twice ten million years have passed away,

Since o'er my sandy bed washed the Devonian Sea.

How insignificant thy "three score years and ten"!—

Yet, like thy "three score years and ten," this twice

Ten millions is but a fraction of the time gone by.

E'en then, as now, the one outstanding fact of all
Was prevalence of universal law.

The sun gave light and heat,

And held his circling satellites in equal poise;

The Moon her monthly passage made

About the turning Earth;

And twice each day the then existing land

Was laved by flowing tides.

We, the living forms, responded

To the urgings of the vital spark,

And passed away.

Nowhere was asked the question, "Why all this?"

Time rolled on with varying change;

Time after time my calcareous bed was lifted up

And sunk again below the ocean's depths.

At last, with mighty rumblings,

The solid crust of Earth was opened,

And 'stead of watery waste,

I found myself upon the mountain side,

While all about was barren rock and desert sand.

Strange creatures roamed the Earth,

And from the lips of one the query came

Of "whence and why and whither."

In boastful arrogance,

Man clothes the Great Unknown with human attributes;

With love; with hate; with lust of power

And childlike jealousy;

He would pretend the world is ruled;

Demands to know the wherefore of his being;

Why he should suffer pain;

And sacrificial altars builds, and temples rears,

*Suggested by the finding of a fossil mollusk in the mountains of Arizona.

To appease the wrath Divine or win His favor.
 In blind conceit he asks to be exempt from Law,
 And he and his be ruled by special favor.
 But from the brooding silence of immensity.
 There comes no answer.
 Thy part consists in humble acquiescence
 In the things that be;
 In trust complete that all that is, is well.
 Be not afraid.
 In childlike confidence entrust thy future
 To the First Great Cause;
 Ask if thou wilt, as ask thou surely must,
 The whence of thy existence;
 Extend thy study to the Universe at large
 And try to solve the plan:
Console thyself that, of it all, thou art a part;
 That of the Eternal Energy that moves it all,
 Thou art a spark.

Death of Weichselbaum.—The eminent Viennese pathological anatomist died October 28 last in the 76th year of life. He was born in 1845, the son of a simple country cooper. He remained to the last proud of the simple life, regarding his subsequent career as the logical outcome of his early environment. His preliminary education ended with a gymnasium course at Krems in 1863. Thence he repaired to Vienna to begin the study of medicine at the University, which he completed in 1869. Up to 1883 he fulfilled various duties, becoming an army physician and eventually the assistant to one of Rokitsky's pupils, who was pathologist to a hospital. At the latter, the Josephine, he also served as operating surgeon and internist, specializing later in military medicine and sanitation. He was for a time instructor in the last named discipline at Lemberg. By gradual stages of subordinate work he reached the goal of his ambition as pathologist to the Vienna University in 1893. This chair he held until 1916. His career as author began in 1872. Two subjects to which he early contributed valuable information were the pathology of the pancreas and the action of chronic alcoholic addiction on the testicle. With Koch's discovery of the bacillus he threw himself into the study of bacteriology and was the first to demonstrate the tubercle bacillus to the then sceptical Viennese professors. Later he became identified with the discovery of several important pathogenic bacteria, the *Diplococcus lanceolatus* of a form of pneumonia, and the meningococcus of epidemic meningitis. He published over 100 papers on pathological histology, bacteriology, and epidemiology, and was one of the world's great authorities on and crusaders against tuberculosis.

Eulogy of Pozzi.—On January 19, 1921, Professor Faure pronounced a eulogy of this illustrious surgeon who was murdered in 1916 by an unbalanced patient. (*Progrès Médical*, Jan. 29, 1916, xlix, 5.) Pozzi was born in Bergerac in 1846 of Protestant stock, his father having been a clergyman. The eulogist and the deceased had been schoolmates. He came to Paris in 1861, where lived the well-known physician, Laboulbène, his cousin, who acted as his preceptor. While still interne, the war of 1870 surprised him. This he fought through and was wounded, lying in the Necker Hospital during the siege. Later he resumed his internate at the Charité

and was thrown early into comradeship with Gosse and A. Robin, men who later were to be famous in surgery and medicine, respectively. The latter, who attended him at his death, experienced the most bitter moment of his career, for the two had been intimate friends for fifty years. In 1875, still an interne, he came under Paul Broca, and, while yet in his internate, he made friends with many of the most distinguished men in Paris, artists, literati, and actors. Among the latter was Mounet-Sully, with whom he became intimate. Through his life he was a lover of all the fine arts, and his home was a veritable art museum. He visited, among other celebrities, Lister and Billroth. Gynecology he chose as his life work. He developed a passion for travel, visiting both Americas and spending much of his time in the Mediterranean countries, including the Holy Land and Egypt. These were not the flying trips of the tourist, but residential sojourns. He was 70 years old when he was slain. Among others, Clemenceau was at his bedside. The operation to save his life is described in full. Four bullets had caused ten intestinal perforations. The operation was done under local anesthesia, so his mind was clear to the end, and he expressed his last wishes, one of which was to be buried in his native town.

Magendie and Experimental Pharmacology.—Recently there has been a slight revival in our interest in the activities of Magendie, who was in the midst of his career as a pioneer a century ago. It has been shown that his great eminence as a physiologist was dimmed by the career of his pupil Claude Bernard and recently we have noted the announcement that he anticipated the discovery of vitamins by at least seventy-five years. This statement we have been unable to verify because the second edition of his "Physiology" bearing the date 1836 is not accessible to us. The chief credit awarded to Magendie both in his time and ever since has been in the domain of experimental pharmacology. In the *Gazette hebdomadaire des sciences médicales de Bordeaux* for December 12, 1920, xli, 50, Massias gives a resume of his work in this field. Magendie's "Formulaire" appeared in 1825 and went through eight editions in ten years. It dealt entirely with newly discovered drugs and gave instructions for their preparation. He tested these new remedies on patients in the Salpêtrière and Hotel-Dieu. He experimented on himself and never hesitated to dose himself with any drug which proved innocuous to animals. He experimented with nux vomica before Pelletier and Caven-
 tou had isolated its alkaloids, this work going back to 1809. In 1818 he introduced morphine into therapeutics. He followed up the various discoveries of Pelletier, such as narceine, codeine and emetine, testing their pharmacological and therapeutic activities. In 1826 he devised the earliest soda mint tablets. He was the first to test quinine in pernicious fevers (1821) and in 1817 advocated prussic acid for cough, and was a pioneer in iodine therapy. He seldom wasted time on substances which failed later to make good; perhaps his advocacy of gold salts came the nearest to a mistake. Nor did he overlook the importance of any discovery by his contemporaries. Leroyer discovered the action of digitalis, and Magendie at once recognized its importance.

FUNDAMENTAL PRINCIPLES OF THORACIC SURGERY.*

By WILLY MEYER, M.D.,
NEW YORK.

GENTLEMEN: To preside over the annual meeting a second time is a privilege I had not expected. Let me assure you that I am deeply sensible of the honor conferred and that I gratefully appreciate your confidence.

No other chapter of surgery has received as great an impetus by the late war as has thoracic surgery. One of the principal reasons for this phenomenon has been the fact that colleagues who formerly had paid little or no attention to the work within the chest, beyond pleural affections, were suddenly confronted with the necessity of operating upon lungs, heart, diaphragm, mediastinum, etc. Another reason has been the terrible influenza epidemic during the last two years of the war, when the hemolytic streptococcus took the lives of so many soldiers through pneumonia and pleurisy. Since then the question of the best treatment of acute and chronic empyema has again come conspicuously to the front and, up to the present time, is one of the principal topics for discussion on the programs of local and national gatherings.

This broadening of the interest almost looks like the beginning of a new era for thoracic surgery. It leaves the hands of the comparatively few who heretofore enjoyed its fascination, and becomes the common property of the profession at large. Such a moment in its development appears to me peculiarly fitting for retrospection and for emphasizing once more what, I believe, many of us, who have done work in this special field, have come to look upon as its fundamentals.

I have reference to three principles which, to my mind, form the basis for the safe and rapid further evolution of thoracic surgery. They concern the lessening of and, if possible, the ruling-out completely of the dangers which attach to this branch of operative surgery. These principles are:

1. The avoidance of the acute pneumothorax—acute operative collapse of the lung—during the operation.
2. The avoidance of the acute *post*-operative pneumothorax resulting from our efforts to render harmless by drainage the exudate which is the response of the pleural leaves to exposure and manipulation.

*Presidential address before the third annual meeting of the American Association for Thoracic Surgery, New Orleans, La., May 1, 1920.

These two points have already been discussed by me in a paper read before the Southern Minnesota Medical Ass'n at Rochester, Minn., on June 23, 1919.¹

Since that time the hard school of experience has again brought home to me another lesson, a lesson which deserves to be laid down as the third principle, and is still more necessary to keep constantly in mind in the surgery of the thorax, than in the surgery of other parts of the body, namely, the importance of

3. The avoidance—as far as it is possible—of everything that might favor the development of a post-operative pneumonia.
1. The Avoidance of the Acute Operative Collapse of the Lung in Thoracic Operations.*

We all know that surgeons called upon to operate during the world war near the front for injuries of pleura and intrathoracic organs were obliged to do so on basis of their every-day's surgical experience, many of them without special preparation for thoracic work. If then, in spite of stress and outward difficulties, such operations were followed by success, it is not difficult to understand that these surgeons should come to the conclusion that, after all, thoracic operations were not different from surgical interference in other parts of the body; or, expressed in other words, that arrangements for maintaining the physiological difference in air-pressure during the surgeon's intrathoracic work, demanded as essentially necessary by other medical men, were superfluous.

In my presidential address before the second annual meeting of our Association at Atlantic City, June 9, 1919, I tried to show the fallacy of such a sweeping conclusion on basis of war experience. I emphasized that it was not conducive to the proper evolution of thoracic surgery, to generalize from the experience made in one single chapter—traumatic chest surgery—to the entire, large field of operative intervention upon all the viscera of the thorax.

The work done near the front, wonderful and admirable as it appears, was, after all, emergency work. It did not permit of the careful individualizing we are wont to practise at the hospitals in times of peace. As in the latter we have the necessary time and opportunity at our hospitals, to give the patients the benefit of the advances made within the last sixteen years, it seems to me it is our duty to do so. Every surgeon preparing to operate on any one of the intrathoracic organs should, I think,

*For the sake of clearness, it seems wise to me, to more often substitute the term "acute operative collapse of the lung" for "acute operative pneumothorax."

take the trouble to first study the dangers of the acute operative collapse of the lung which inevitably occurs on incising a "virgin pleural cavity," that means a pleural cavity, which had never been the seat of inflammation and therefore shows nowhere any adhesion between its pulmonary and costal leaves. He would then recognize the danger to which he was exposing his patient when not guarding against this accident by employing one of the four methods of differential air-pressure which, fortunately, now are at our disposal for this purpose. True, fully one half of our patients seem to be able to stand the sudden collapse of the lung. But, are we able to tell *beforehand* who will overcome the concomitant risk and who will succumb to it? Can we know *beforehand* whether we have to transgress that length of safety in our incision which Graham and Bell, by ingenious mathematical deduction, have established? Is it not, therefore, self-evident, that suitable arrangements should be made for safe intrathoracic operative work, so long as we have ample time to prepare for and meet the dangers ahead?

Not long ago I talked to a colleague at the close of a meeting in which he had just stated before a large audience, that lung surgery could well be done **without the use of differential air-pressure**. He said to me: "I know it is better for the patient to avoid the lung collapse; still I believe, we can get along without air-pressure in lung surgery." I agree with him only to the extent that emergency cases are concerned—cases of traumatism that demand prompt surgical action—out in the country; but at home, at our hospitals, we should nowadays be prepared to give our patient the benefit of what science offers for the sure avoidance of one of the principal dangers confronting him.

Besides, by making use of a differential pressure apparatus we are enabled to thoroughly distend the lung at will and make it collapse again, that is to say, carry out lung gymnastics in the course of the operation, a procedure which, when intermittently and methodically done, represents one of the most powerful heart stimulants on a physical basis. And what, if a *double* pneumothorax occurs in the course of an intrathoracic operation, accidentally or intentionally? What, if the adhesions between the visceral and costal pleura are in the way and have to be severed, if the lung has to be pushed aside in order to reach the seat of the disease? Preparing for such emergencies by the use of apparatus means safe-guarding the patient's welfare.

2. The Avoidance of the Acute Post-Operative Collapse of the Lung in Thoracic Operations—Airtight Thoracic Drainage.

Observations on the post-operative course in quite a number of patients subjected to intrathoracic interference have shown that it is for the patient's best, here as elsewhere, to follow the principles of general surgery. In the thorax, more than in any other part of the body, post-operative drainage is desirable, often clearly indicated on account of the great tendency of the pleura to form an exudate. But, draining the chest immediately after an intrathoracic operation also means collapse of the lung, except it can be done in such a way that the air is prevented from entering the

thoracic cavity through or alongside of the drain. In other words, the drainage must be "airtight," that is to say, while the amount of air, present in the chest at the conclusion of the operation, must find a ready outlet, no air must enter. Such a procedure not only allows the lung to distend immediately after the completion of the operation and to remain distended, but it gives exit to any exudate that may form. This exudate is sterile only in exceptional instances. Airtight thoracic drainage, therefore, fulfills two important demands simultaneously.

The principal points of airtight thoracic drainage have been brought out by me before. What Buelau taught in 1891, as being the most desirable procedure in the treatment of empyema, we have come to accept—in a round-about way, I might say, and independently of Buelau's teachings—as the safest procedure for *every* intrathoracic operation, on basis of careful observations during the after-treatment and on basis of the results of the thoracic work of ourselves and others.

Kenyon's original work on the drainage of empyema in children, adapted by myself to intrathoracic operations in general, is, as a careful study of the literature has shown me, *Buelau's principle*, carried out in a somewhat different way. In order to emphasize the principle as such, I propose that we drop the authors' names altogether and call the procedure simply "Airtight Thoracic Drainage."

In carrying out this drainage, best, to my mind, as just stated, in *every case* of thoracic operation, we save our patients danger, trouble and pain. Besides, it is easily performed and gives fullest satisfaction to both patient and surgeon alike.

Absolute airtightness of the drainage tube is required after the operation for the first two to three days only, in order to give the lung the chance for proper distention and also to favor the formation of adhesions between pulmonary and costal pleura. These requirements the method fulfills, as clinical observation has abundantly shown. It is remarkable to see how quickly these adhesions take place.

And now as to the third principle, the avoidance of pneumonia, the goal also of our every-day's work.

3. The Avoidance of Post-Operative Pneumonia in Thoracic Operations.

It is natural to assume that by handling the lung and working on and next to it, the danger of the development of an inflammation in this organ should be increased.

At the second annual meeting of this Association, last year, Dr. S. J. Meltzer read a paper on "The Integrity of the Vagus Nerves as a Factor in Pneumonia," the complication which has marred and is daily marring so many efforts of the surgeon, particularly in thoracic surgery. To Meltzer the hypothesis seems plausible: that the resistance of the lung tissue to infection depends, among other things, upon the integrity of the vasodilator nerves of the lung. Should not the handling in intrathoracic work of the pneumogastrics, also often direct injury to their main trunks as well as their many branches, contribute to the post-operative occurrence of pneumonitis?

What I believe will greatly help to avoid a post-operative pneumonia in thoracic work is:

1. The selection of the proper type of differential pressure apparatus for general anesthesia in the given case;
2. Carefully planned preparation against possibly arising difficulties, by placing within easy reach the devices required to meet them;
3. The more frequent and persistent use of regional and local anesthesia during the entire operation in order to avoid aspiration of intrabronchial contents into the lung tissue proper, as so frequently occurs during general anesthesia;
4. Thorough clearing of the bronchial tree by means of aspiration, at the hands of a trained bronchoscopist, just before the operation. Such pre-operative preparation, of course, refers only to patients suffering from chronic, non-tuberculous, suppurative lung disease, *i. e.*, patients that have become accustomed to the introduction of the bronchoscope.
5. Further experimental work on cocainization of the pneumogastric nerve or nerves, above as well as below the aortic arch.

If the above mentioned desiderata: avoidance of sudden unintended and prolonged lung collapse during and after the operation, and avoidance of post-operative pneumonia, have been fulfilled, furthermore, if airtight post-operative drainage has been arranged for, and if surgeons are ready to carry out what the experience of the last 16 years has taught us, then, it seems to me, the safe and rapid evolution of thoracic surgery will be assured.

ROUTES OF ACCESS TO THE HEART.

LESSONS GATHERED FROM THE EXPERIENCES OF THE WORLD WAR.*

By RUDOLPH MATAS, M.D., F.A.C.S.,
NEW ORLEANS, LA.

PROFESSOR OF SURGERY, TULANE UNIVERSITY.

THE experience of the late war and the extraordinary increase in the number of casualties caused by the explosion of artillery projectiles (shell fragments, shrapnel, etc.), machine gun fire, and other foreign bodies, have virtually created a new chapter in the history of cardiac surgery. Apart from the greater frequency of the lesions of the heart by projectiles, migrating foreign bodies in the circulation, etc., the frequent survival of the wounded from the immediate effects of the primary trauma with retained missiles in the heart, has revealed a greater relative tolerance for these bodies than was previously suspected. The presence of these projectiles, as demonstrated by radiologic methods of investigation, has created a group of post-traumatic cases which come to the surgeon in a cold or latent stage in which the symptomatology

*Read before the American Association for Thoracic Surgery at New Orleans, La., on May 1, 1920. (A condensed report.)

and indications for surgical interference are very different from those offered by the immediate phenomena of the initial injury. In these cases the problem of diagnosis does not confront the surgeon with perplexing doubts. The presence of the missile in the heart or its immediate vicinity is proof positive of the lesion. Furthermore, the anatomical localization of the projectile or the foreign body has been localized in the heart chambers or the heart muscle by the radiologist—sometimes with almost uncanny precision and detail. The condition of the patient is not that of a shocked, exsanguinated, and often asphyxiated individual, battling for existence, giving the surgeon only a few precious moments to save life. These patients, on the contrary, come to the surgeon weeks, months, and years after the original injury has been inflicted, their complaints depending more or less upon the cardiovascular and respiratory disturbances and the gravity and persistence of the symptoms which are manifested after recovery from the primary effect of the trauma has been assured. Time, therefore, is afforded for the most thorough and satisfactory radiological and physical investigation, and for the most deliberate, calm judgment on the surgical indications in the event that the extraction of the projectile is deemed necessary or justifiable.

The lessons which have a direct bearing upon the surgery of the heart in general, and with reference to the extraction of foreign bodies in particular, may be briefly summarized into:

1. The indispensable association and collaboration of the radiologist with the surgeon for diagnostic and operative purposes.
2. The proved efficiency of this collaboration has added vastly to the safety of the intrathoracic manipulations and to procedures for the extraction of foreign bodies, which hitherto have been regarded as largely impracticable if not visionary.
3. Modifications in the technique of thoracotomy which utilize the older suggestions and methods have been revised and extended in the light of a new and larger experience.
4. The disregard of the pleura and of the risks of acute surgical pneumothorax, contrary to all preconceived notions of the gravity of this complication in ante bellum days.

In regard to radiological methods, all agree that radioscopy with the fluoroscopic screen is far more important than radiography with plates. There is a great difference in the methods of radiology utilized for the localization of foreign bodies among the leading operators, as seen by comparing the technique of Pierre Duval, René LeFort, Ombredanne and LeDoux Lebard, Marion, Mauclair, and Petit de la Villeon, and yet each has a claim for a certain measure of success.

In regard to pneumothorax, before the war we were deeply concerned with the risks and danger of the sudden admission of air into the pleura. Then the division of thoracic operations into *extra* and *intra* pleural was of great significance. The fear of traumatic or acute surgical pneumothorax dominated the minds of most surgeons, and the many devices and apparatus invented for operating under *hyper* and *hypo* pressure (Sauerbruch, Brauer, W. Meyer, Matas-Smyth, etc.) attest the conviction that everywhere prevailed to the effect that the

sudden collapse of the lung after the entrance of air into the pleura was a perilous complication which stood in the way of the progress of thoracic surgery. The introduction of the Meltzer-Auer principle of ventilation of the lung by intratracheal insufflation, regardless of the intrapulmonary tension, was a great advance and relieved many operating rooms of the cumbersome appliances which were used to obtain *plus* or *minus* tension in the lung. But even this last method, which is still a precious resource in counteracting the effects of *bilateral* pneumothorax, and whenever the mechanism of respiration is suspended was found unnecessary by the pioneer French military surgeons of the recent war, who unhesitatingly and freely opened the pleura whenever they deemed this necessary for their purpose.

This was the experience of Duval, Marion, LeFort, de la Villeon, and the majority of the operators on the French side, and of Moynihan and others on the British side, who seem to have confirmed the old views long ago entertained by Bazy, Delagenière, and Marion, that pneumothorax could be disregarded as a vital factor in thoracic surgery.

What we have learned of the tolerance of the pleura and lung for pneumothorax, applies as well to the injuries of the heart in which the pleura has been coincidentally opened and pneumothorax exists as a complication (61 per cent. of the cases). In such cases there is no reason why the heart and pericardium should not be exposed by the quickest and freest intrapleural thoracotomy. On the other hand, when the pleura is not involved, and there is no pneumothorax and the heart must be reached and freely exposed to extract the projectile embedded in the myocardium or held within its cavities, it is proper to consider the addition of pneumothorax as a complication which should be avoided if possible.

The object of the author, in this essay, is to consider the routes of access by which the heart can be made more accessible to surgical manipulation in all its parts, including the great vessels at its root. The procedures which have been utilized most frequently in the late war, especially by the French surgeons, who have had the greatest experience in this department of surgery, are reviewed. The reports of the many operations which have been performed for the removal of foreign bodies in the heart or at the root of the great vessels, shows a great variation and discrepancy even among the most experienced operators. There is, for instance, a great leap between the practice of LeFort, who insists upon the importance of a large open door and plenty of light, and who opens a large fenestra by a trap door osteoplastic flap, including the cartilages from the third to the fifth ribs to the left of the sternum, and the small button hole intercostal incision barely long enough to admit a long narrow forceps, that Petit de la Villeon has used so successfully in the extraction of pulmonary and mediastinal projectiles.

It is evident from the compilation of the numerous case records that the methods adopted by the individual surgeons have varied according to conditions. But it is also quite evident that while the intrapleural methods are necessary and unavoidable in dealing with pulmonary or mediastinal projectiles,

it is *very questionable* in the particular class under consideration (retained heart projectiles in the *latent* or *cold* stage), whether the pleura should be opened to expose the heart. Even Duval, the most fearless advocate of intrapleural manipulations in lung surgery, regards an acute pneumothorax as an undesirable complication in cardiac cases, and this is one of his reasons for advising his mediasternal abdominal pericardiotomy, which freely exposes the heart and the great vessels in the pericardium without opening the pleura.

The speaker then reviewed the methods of thoracic approach to the heart from the point of view of recent heart injuries, complicated by coexistent pneumothorax and those operated in the *latent* or *cold* stage without pneumothorax. For recent cardiac injuries complicated by pulmonary hemorrhage and hemothorax, the intercostal incision of Spangaro (1906) which he (Matas) had first introduced to English speaking readers (*Trans. Southern Surg. Ass'n*, 1907, and *Keen's Surgery* Vol. V, 1909) offered the greatest advantage. It could be made as large as necessary following the intercostal space and could be widened as much as necessary by forcible retraction, with rib spreaders coupled with a section of the sternal ends of the cartilages above and below the intercostal space. By this procedure, free access was given to the heart and lungs. LeFort has carefully studied this procedure since the war and has resorted to it with advantage, though he has utilized the large trap door osteoplastic flap of Delorme when a very large opening was required. Experience has taught that in certain cases, none of the parasternal or lateral trap doors, or the intercostal incision with division of the cartilage would suffice to expose the retrosternal regions of the heart and the great vessels at its base, without dangerous traction on the organ, and for this reason several operators have been compelled to make supplementary sternal resections (Fontan, Terrier, Raymond, Marion, Podrez, Rydgyier, Cantas, and even Delorme.) The obstacle offered by the sternum to a complete exposure of the heart (base, auricles, posterior surface, and great vessels) is overcome by the medio-sternal pericardiotomy first suggested by Milton of Cairo (1897), subsequently modified and successfully applied by Rehn (1914) but made really practical and effective by Duval and his associates Barnsby and H. and B. Barastys. The technique of this operation was illustrated by the speaker with lantern slides from the description given by Pierre Duval and the Barastys in the *Presse Médicale* of August 29, 1918, under the title of "Median Thoraco-abdominal Pericardiotomy."

The Duval-Barastys operation essentially consists in: (1) A median incision from the level of the third costal cartilage to a point in the linea alba, midway between the tip of the xyphoid cartilage and the umbilicus. After cutting the skin to the sternum, the incision is carried through the abdominal aponeurosis and between the recti, down to, but *not* through the peritoneum. (2) The upper insertions of both recti are detached from the edge of the ensiform cartilage, exactly through the median line and the posterior surface of the ensiform, the attachments of the diaphragm also being cut away from the cartilage. (3) Two fingers of the left hand are inserted and pushed from below upwards and behind the xyphoid, and then behind the sternum up to the level of the third costal cartilage, the fingers closely following the posterior surface of the bone. In this way the pericardium is detached from the retrosternal connective tissue. By separating the fingers slightly, the two pleural cul-de-sacs are pushed away from the midline and laterally to the under surface of the costal cartilages. (4) The sternum is then split in the midline with a large chisel (the speaker

prefers the giant sternotomy of Hudson, which does better and quicker work) beginning from the tip of the xiphoid and ending on a level with the third costal cartilage. At this level a transverse section of the sternum is made, leaving the manubrium attached to the clavicle and to the first and second costal cartilages. (5) The two halves of the sternum are now spread open, lifted, and bent out with retractors (the hands of assistants are preferable), care being taken not to fracture the cartilages. Through this large vertical space the pleural cul-de-sac and pericardium are recognized, displaced and detached from the thoracic wall with gentle gauze pressure to avoid any tearing of the pleura. (6) Laparotomy and pericardiectomy: the peritoneum is now opened in the mid line. By inclining the incision a little to the left and immediately along the insertion of the diaphragm to the chest wall, the pleura will be seen to diverge, leaving a very considerable and safe interspace between them. The pericardium is now held up with two forceps and divided in the midline with straight, sharp, but blunt pointed scissors; the pericardium is now split its full length to the root of the great vessels. The pleural cul-de-sacs are now safe and need not be considered. (7) Section of the diaphragm. Between the pericardial and peritoneal sacs, the diaphragm still remains as a horizontal partition holding the two halves of the divided xiphoid in place. The scissors are again introduced and the diaphragm is divided up to the level of the suspensory ligament. The sternal halves are then pulled apart and by lifting them up and bending them outward upon their cartilaginous attachments, they widely open the retrosternal space.

It is like opening a book—exhibiting the heart with the great vessels at its base, in full view before the operator. The ventricles, auricles, aorta, and vena cava, anterior and posterior surfaces of the heart are thus made easily accessible to any manipulation without requiring exteriorization, traction or torsion of the organ.

* * * * *

After the extraction of the projectile or suture of a cardiac wound, the operation is concluded by the suture of the diaphragm, then of the abdominal incision and of the pericardium. The sternal halves are replaced and held in contact by aponeurotic sutures without bone suture support. Finally, a continuous or interrupted suture closes the skin without drainage.*

The chief and only objection that can be made to this operation is its apparent magnitude, but this objection is more apparent than real. It is certainly not a greater trauma than is involved in making a large trap door osteoplastic flap on the Délorne plan, which at once creates a pneumothorax, and it is surely less bloody, as the section is made strictly in the midline. It is, however, an operation which is to be reserved for the extraction of foreign bodies in the heart, pericardium, or great vessels at its base, in the cold stage when there is

no infection or complicating pneumothorax and the patient has had time to recover from the effects of the primary injury. The feasibility of this procedure is not based on purely cadaveric studies, but by three successive operations on the living subject.

The first case was reported by Duval and Barasty to the Société de Chirurgie on June 26, 1918 (*Bull. et Mém. de la Société de Chirurg.*, No. 23, July 2, 1918). The operation was performed within a week after a French soldier had been wounded in the chest by a German spitz bullet. The bullet had entered the left thorax on a level with the seventh rib in the anterior axillary line. He had lost consciousness for a while and had a light hemoptysis—but no other extraordinary symptoms, except occasional intermissions in the pulse beat, and later, pains in the precordia which were aggravated by every movement or effort, and especially when attempting to sit down. In the course of a radiologic examination with the fluoroscopic screen, the bullet was seen playing up and down along the vena cava, gyrating, turning on its axis and looping in the venous currents with excursions which extended from the level of the diaphragm to the right auricle, into which it entered and escaped with extraordinary velocity. The mediosternal operation as above described, was adopted, and the bullet felt through the pericardium in the inferior vena cava. After several unsuccessful attempts to grasp it, Duval finally succeeded in pinching it through the walls of the vein with his fingers and holding it at the junction of the cava with the auricle. After encircling the projecting body with a purse string suture, he incised the vein and extracted the bullet with a forceps. The bleeding was immediately controlled by tightening the suture. The heart behaved admirably throughout, though the pulse went up to 140, but rapidly fell to 100 shortly after the operation had been completed. A liter of blood was evacuated from the left pleura on the fifth day. Nine days had elapsed since the operation and the patient was progressing rapidly towards recovery, though he had a pericardial friction and signs of a small pulmonary infarct in the right lung. It is presumed that the bullet had entered through the left lung, perforated the left ventricle, the interventricular septum, then entered the right ventricle and had been ejected through the tricuspid orifice into the right auricle, from which it moved against the current into the inferior cava where it was kept in constant motion by the force of the blood stream. This case is unique in its way and is probably the first in which a mobile migratory bullet has been extracted from the inferior vena cava through the pericardium. It would seem impossible to have accomplished its extraction by any other way than through the large and direct opening offered by the amplified mediosternal thoracotomy of Duval.

* * * * *

*Full details of the operation with illustrations, are given in the chapter on the "Military Surgery of the Vascular System" in Vol. VII of Keen's Surgery which has just been issued (March, 1921) by the press of Messrs. W. B. Saunders Co., publishers, to whose courtesy the author is indebted for permission to incorporate much of the matter which appears in this text.

It is a different story in the second case—that of Barbier and Gujon (*Bull. et Mém. Soc. de Chirurgie*, No. 38, Dec. 24, 1918). In this soldier the bullet entered the heart directly from back in the left thoracic region. When he was wounded the patient complained of intense pain in the heart and in two minutes fell unconscious and remained in this condition for twelve hours. He was transported

in this grave condition and reached Barbier's station at Traves two and a half hours after the injury. His condition was then alarming; shallow respiration, intense dyspnea, cyanosis. Pulse, small, irregular, 80 to 90. The radiographic examination revealed a bullet which was lodged either in the walls of the heart or fixed in one of its cavities. Barbier operated *twenty-three days* after the injury. The bullet was located in the *posterior* wall of the heart midway between the apex and the base, in the wall of the right ventricle. Barbier clamped the heart between his fingers and placed two prophylactic sutures, one above, the other below the projectile; he then incised the myocardium and extracted the bullet. A jet of black blood spurted; evidently the projectile had penetrated the right ventricle. The two catgut sutures were tied at once, and three additional sutures completed the hemostasis. The wounds in the pericardium and other parts were closed without drainage and post-operative sequelæ were remarkably mild. Thirty days after the operation the patient had recovered completely with no physical signs or symptoms in the heart or elsewhere to show for his injury.

Barbier regards the method of approach by Duval's median thoracoabdominal pericardiotomy as ideal on account of the ease of its execution and the great working space it gives to the operator.

* * * * *

The third case is also very remarkable in many ways. In this case, reported by H. Rouvillois: (*Bull. et Mém. Soc. de Chirurg.*, No. 18, July 3, 1919), the missile was removed $4\frac{1}{2}$ years after it had entered the heart. The patient, a soldier of 23 years, was wounded early in the war by a German spitz, which penetrated the anterior surface of the chest, a finger's breadth from the ensiform cartilage. As he was struck, he felt a violent pain as if he had been "punched in the pit of the stomach with a fist," but this was only for an instant, after which he was practically free from symptoms. After resting eight days in the field hospital at the front, he was able to *ride 60 kilometers on his bicycle* without exhibiting any sign or symptom of any consequence, until three days after the ride, when he felt some pain in the wound, which was of short duration. He was sent to the rear where a radiologic examination was made, which seemed to show the bullet near the surface, and several efforts were made to extract it, but they failed, as the bullet could not be found. He returned to the front (four months after the injury), when he realized that any severe exertion brought about palpitations. He was made a prisoner in April and was then compelled to do hard work, which brought about great palpitation and precordial distress. He was sent back to France in November, 1918 (three months after the injury); disabled, and in extreme weakness with fainting spells, cold sweats, vertigo, and palpitations, which steadily grew worse. With all this, his physical heart signs were negative, no cardiac murmurs and a good regular pulse, when he was quiet and avoided undue exertion.

The radiologic examination revealed a bullet which appeared to be in the immediate vicinity of the heart and probably in the pericardium.

He was operated on April 11, 1919. The Duval mediosternal section was adopted. The heart proved

normal in appearance, but on palpation the bullet was detected in the wall of the right ventricle, to the right of the apex. The extraction of this bullet from its bed proved to be an extremely laborious and trying procedure, as the bullet could not be enucleated or shelled out. It was finally mobilized with a periostome or bone scraper, which exposed it sufficiently to allow a strong Kocher forceps to extract it. The bullet was covered with a layer of calcareous incrustation which had literally fused it to its surroundings. The bleeding that followed this remarkable extraction was easily controlled with prophylactic hemostatic sutures. The recovery and convalescence of the patient was also remarkably rapid and perfect.

* * * * *

In sharp and striking contrast with the methods which stand for a "wide-open door and plenty of light" in the thorax for the treatment of heart wounds and the extraction of cardiac projectiles, we find the method of Petit de la Villeon. The peculiarity of this method is that it searches for intrathoracic projectiles under the fluoroscopic screen and extracts them through the smallest button-hole openings. The openings are made in the intercostal spaces after a careful localization of the projectile, and with this in constant view, a long blunt-pointed forceps follows it wherever it may be, and extracts it. This method, which is known as the method of the "forceps under screen," is one of the most extraordinary and sensational developments of this war's experience. De la Villeon first began to apply this method early in the war in the extraction of projectiles lost in the extremities. His success was so great that he tried it in the chest for the removal of foreign bodies in the lung and mediastinum. This was done for the first time on October 27, 1915, with remarkable success, not only by the distinguished originator himself, but by a large number of surgeons who have followed in his footsteps. This emboldened de la Villeon to attempt the extraction of bullets and other foreign bodies from the heart and pericardium. On May 28, 1919, he reported the extraction of 14 projectiles from the cardiopericardial or cardiopulmonary areas. All of these patients were relieved of their projectiles and were up and about in an astonishingly short time (3 to 5 days) after the operation.

In reply to the numerous criticisms bearing on the uncertain and adventurous nature of this procedure, he explained to the Société de Chirurgie what he regarded as the limitations of the method in its applications to cardiopericardial projectiles. Only missiles attached to the surface of the heart could be attacked by this method. He would not dream of removing any projectiles which penetrated the heart cavities and he would not attempt the extraction of bodies embedded in the auricles or right ventricle because he realized full well the dangers of hemorrhage from dislodging such bodies. The "permissible zone" of attack was the pericardium, the thick wall of the left ventricle, and the thicker cone of the apex. In any case, the depth of penetration of the forceps should never exceed the more superficial layers of the myocardium and not deeper than 3 mm. from the visceral layer of the pericardium. How he was able to regulate this depth of penetration by the screen, or how he was to overcome

the tough resistance of the pericardium, he could not well explain. Beyond this permissible zone, it would be folly to attempt to penetrate with a forceps. The auricles, right ventricle, the interventricular grooves, and the walls of the vena cava, constituted a forbidden zone which should not be trespassed upon by this method. Projectiles in these areas can only be extracted with safety by the open methods of thoracotomy. In proof that he had actually extracted projectiles from the myocardium, he stated that in two cases the projectiles had brought with them fragments of tissue which, on microscopic section, were shown to be typical myocardial fibers.

It is easy to understand that such a procedure could find no application in the surgery of the heart, no matter how useful, in the hands of an expert, the method has proved to be in the lung and other less vital localities. It is not surprising that on several occasions the procedure, as applied to the heart, even in the restricted way in which de la Villeon applies it, should have been received with much doubt and scant favor by the most representative French surgeons (Pierre Duval, Broca, Tuffier, La-Pointe, Hartmann, *et al.*). The consensus of opinion, as formulated at the close of the discussion, was summed up by Hartmann, who stated that "no matter how satisfactory this method had proved to be in the lung and in other parts of the body, it had no place in the surgery of the heart, and should not be employed for the removal of cardiac projectiles." Whatever the shortcomings and obvious dangers of this method in cardiac surgery, there can be no question that, in other parts, it has yielded almost incredible results in the hands of its master and his immediate followers. There is no procedure that is so largely dependent for its success upon the personal equation, the skill and experience of the operator.

In regard to the results of operations for the removal of missiles from the heart (cardiotomies) chiefly by thoracotomies which were complicated with pneumothorax, hemothorax, or other lesions, we find that Délorne had gathered from French military sources during the war and up to September 25, 1918, twenty-five cases (*Bull. Académie de Med.*, Sept. 25, 1917). Of the first seventeen cases which were reported in detail in his exhaustive memoirs, he found that ten of the missiles had been removed from the right ventricle, three from the right auricle, two from the left ventricle, and one from the left auricle. The result in thirteen cases was surprising: ten recoveries and three deaths (76.1 per cent. recoveries). René LeFort states that he had removed eleven foreign bodies from the heart in the course of nine operations; in two cases from the heart cavities, with only one death.

The gross comparative statistics of the late or delayed operations for cardiac projectiles, including the *operated* and *unoperated* cases, are summed up to December, 1918, by Pierre Duval, who has gathered most of his material from a monograph by Rossi. According to Duval's compilation, the total number of reported war projectiles in the heart up to 1918 (*Bull. et Mém. Soc. de Chirurg.*, Dec. 24, 1918) is 62.

These figures do not include the cases in which the projectiles found their way into the heart cavities through the peripheral or extra cardiac avenues

of the circulation. Of this group, Duval finds twelve cases with nine deaths. Neither does he include la Villeon's cases, who on May 25, 1919 (*Bull. et Mém. Soc. de Chirurg.*, No. 18, June 3, 1918), reported the extraction of fourteen projectiles from the cardiopericardial or cardiopulmonary area, by his method of the "pince sous écran"; none of these were intracardiac, but were lodged in the vicinity of the heart and large vessels. Two of these he claims were parietal (myocardial), but there is no convincing proof of this.

Going back to Duval's statistics of the cardioto-mies by open methods, he found that of the 62 cases, 39 were parietal (mural). Of these, 16 were operated, with 14 recoveries and 2 deaths; 23 were not operated, with 23 recoveries and no deaths. There were 23 cases of projectiles retained in the heart cavities (*intracavitary projectiles*), of which 10 were operated, with 7 recoveries and 3 deaths; not operated, 13, with 12 recoveries and 1 death.

Judging by statistics, it plainly follows that non-intervention should be the rule. Evidently, however, the indications for operation cannot be formulated by mere statistics. The indications for operation are not amenable to rules. The indication must be based upon the individual prognosis from the point of view of the condition of the patient, the degree and duration of his disability. It is only when life is threatened by the presence of the projectile, and the patient thoroughly understands his danger as well as the risks of the operation that this can be regarded as justifiable. If an operation is decided upon, it is then that the advances and the new knowledge of the technique acquired by the experience of the late war will prove to be an invaluable acquisition.

THE ADVANTAGE OF MENTAL THERAPY IN ORGANIC NERVOUS DISORDERS.

By L. PIERCE CLARK, M.D.

NEW YORK.

(Concluded from page 556.)

III.—ESSENTIAL AND SYMPTOMATIC EPILEPSY.

WHILE it must be generally admitted that essential epilepsy is an organic disease, no one distinctive brain lesion when present has been generally agreed upon to be common to all. As in many other brain disorders, the lesions found must be considered as the symptomatic pathology of the disease—more an effect than a cause. In view of the fact that morphologic and microscopic studies lend so little aid to the ultimate understanding of the true disorder, many have turned their attention to its psychogenic aspects. In so doing the majority of workers have not been misled into thinking that the fundamental nature of the disease may be revealed by such studies. The real nature of it, like that of gravity and of electricity, may remain equally obscure or hidden. But by such studies we may more definitely reveal its pathogeny by aid of the finer technique of the newer psychology. Of course it is quite absurd to say that we may psychoanalyze away an organic disease any more than that we may do away with constitutional instability of subcortical centers in the spasmodic and tic dis-

orders. It is, however, true that we may analyze away the so-called affect epilepsies, but they really are not epilepsy at all, but forms of psychoneuroses with convulsive symptoms acting as conversion symptoms of the general neurosis. Yet there are affective elements in all cases of essential epilepsy, and to this more or less constant attribute we must ascribe many of the temporary improvements in genuine epileptics by pure psychoanalysis, however difficult and incomplete such analysis may be. However, it is not essentially in this direction that the greatest advantage in the therapy of the disorder has been attained, but rather in the genetic understanding of the epileptic as a personality independent of the more or less obvious character of his chief symptoms, namely, his fits.¹

For many years the epileptic has been known to possess a unique personality, but lately it has been more precisely and accurately defined and we now believe it to be summed up in the statement that he possesses in glaring excess egotism, supersensitiveness and emotional poverty—the latter taken in its broadest aspects. Primarily these faults of character are based upon some fundamental defects of instincts, usually more inherited than acquired. The fault becomes frequently the more patent as the potential epileptic grows up and meets the progressively increasing stresses of life. This renders such individuals extraordinarily susceptible to outbreaks of their disorder for the first time upon slight or no discernible cause. Naturally, then, if we have looked to recovery from the primary fault, we must recognize a tentative pathogeny of the disorder to be a general and constitutional one, a sort of imbalance of cortical and subcortical elements not dissimilar in neurological principles to those more or less generally recognized to subtend the other spasmodic disorders to which we have already alluded. Perhaps the morphologic deterioration found at autopsy is in these tissues most diseased, but this is pure speculation.

If epilepsy, then, is a sort of abiotrophy of a family stock, a recessive and not a dominant, eugenically speaking, one may understand how the pathogeny of the affection may easily outrun the limits of any personal investigation of the individual case. However, we must make the best of a bad situation and plan our therapy as best we can. If, then, we cannot approach the lesion or neural fault on organic grounds by any specific therapy as such, what may we do for it by psychologic means of treatment? But when we do this we radically depart from the idea of again bridging the gap between the somatic cerebral factors underlying the disease and the psychobiologic pathogeny of the disease. Until this gap is filled we cannot hope to solve the real problem of just why epilepsies come about.

Without further concern as to the ultimate pathology of the disorder we shall schematize what may be done with epilepsy by an opportunistic consideration of it as a life reaction disorder, that is, as a psychologic entity. First of all, we cannot hope to radically change the fundamental nature here more than anywhere else but so adapt such a type of individual so he may obviate the more specific manifestations of his attacks and the like epileptic reactions. This is largely a process of

daily education by taking into account the development of the trends of interest within the range of its possibilities. The individual is to be sympathetically encouraged in all activities that concern the broadest development of his narcissistic interest. We do not try to make him a social being as a collectivist with broad interests. Being anti-socially inclined, his life must be built around him as an individualist. In its larger development this enables him to live in harmony with the collectivist though their innate life interests are widely separated. We can do this best by an intensive study of the special aptitudes, both of a conscious and an unconscious nature—his daily conflicts, dreams, and the unconscious motives revealed in the transitory deliria of petit mal seizures. All give us material upon which to work.

Several errors in the empirical training of the past have been to try to make over and change the epileptic character, together with too little personal appeal as an incentive to continued effort, as well as too little variety in the daily life. Many of these attitudes of approach in mental therapy can be best illustrated in a brief citation of individual cases.

The first case cited will be of the simple constitutional sort, the individual showing exquisitely the epileptic makeup. Others will be symptomatic epilepsies, dependent upon organic brain lesions. The manner of approach in either class is not specifically different. One must bear continually in mind here, as over the whole domain of medicine, that the physician's great fault is not that he does not make a careful analysis of the physical disorders which he finds, but that he is too often unduly impressed with the consequences of such positive data for ill and not enough aware of the innate and acquired possibilities of the natural bodily defenses and aptitudes for spontaneous adjustments which the organism as a whole possesses. Less burdened with exact and determinative knowledge of tissue disintegration, the charlatans are able—though with less real grasp of facts, to build a hopeful constructive program out of the positive assets which the patient still possesses and often gain thereby astonishingly good results. It is not that we should know less, but rather more, of the broader significance of all life processes and possibilities. One has but to cite the older gloomy views in regard to a valvular lesion of the heart and the present attitude that such a lesion in itself is not of so very great moment if the organ is sufficiently compensating in structural alterations to give proper functioning.

CASE I¹ is that of a boy of fifteen whose grand mal epilepsy has now been in two periods of arrest, one of seven years (to November, 1918). He had attacks usually in a series of two to ten, and had at least three or four status periods, in one of which he had 150 grand mal attacks in a single day. There was no distinct nervous disorder in the family stock, but many of the paternal relatives possessed the epileptic character. The boy himself had the classic epileptic personality. While it was possible for him to endure the demands of home life with rages and tantrums, later when these had to be repressed at school he could not subordinate his crude individualistic tendencies; he broke into uncontrollable tempers, was punished and sent home. His first grand attack came on one night after a particularly exasperating day at school. After the first attack he still continued at school, with all its

steadily accumulating annoyances, until a month later, when he had five grand attacks in one night. It was then decided to have him leave school, and allow him to go and come as he pleased with his father, who was in the fishery business. Under training treatment and directing his interests from the abstract work at school to a concrete outdoor life he gradually became more tranquil and the attacks ceased.

After an arrest of seven years this boy once more became epileptic. We find the mother anxiously pushing him in the ordinary abstract training at school. He has had three convulsions, the first occurring in November, 1918, the second a year later, and the third in March, 1920. Since this time he has remained free, but there are days when he feels stupid and can do nothing correctly; the parents have now learned to put absolutely no duties upon him at these times, either in school or at home; he complains of his head feeling bad and can hardly recall anything that might have transpired during that period, showing a state of acute exhaustion due to forced efforts at school work.

CASE II is quite unique, inasmuch as it is one of an infantile cerebral hemiplegic who has recovered from his epilepsy or Jacksonian spasm, the only one with this favorable outcome that I have even seen or known of in a large experience. The patient is a man now twenty-six years old, who came under treatment when he was ten. He had a bad family history of actual nervous and mental disorders in the ascendants as well as less defined psychopathic traits. At five years of age, after an attack of smallpox, general septicemia occurred and ended in a left hemiplegia. The convalescence from this serious mishap was prolonged and three months after the initial onset of high fever and convulsions he had an attack of status hemiplegicus unilateris (left) with fever 104° plus. The clinical history showed 47 grand mal attacks in four hours. The attacks began with a Jacksonian onset on the left side and then became general to a slight degree. Since that period he had all varieties of attacks every two or three months in a series of several at each period. Incidentally our patient had what I made special report of at the time, a paradoxical pseudomuscular hypertrophy. The fits were followed by transitory exhaustion palsy. The boy suffered no other physical fault than that mentioned. In makeup he was typically epileptic. Inasmuch as we could do nothing specific to the lesion, long since transixed in a meningitic scar, and realizing the poor prognosis that must be held for such a form of symptomatic epilepsy, we undertook to so regulate and teach the patient the nature of his temperamental defects as to enable him to gain as full and continuous a field of interest as possible. A succession of activities was engaged in without great success until a chicken farm with fruit raising was provided. Around the duties and interests of this demanding occupation our principles of concrete teachings were grouped. After a few months the fear and apprehension of attacks were removed, and the patient kept at his work in spite of warnings of an approaching seizure. When the fits finally did occur after many such aures, he immediately afterward resumed his work. In fact he became so used to his symptoms that they were no real concern to him one way or the other. The convulsions grew less and less frequent and severe until the spasm was confined solely to the left arm and face. The arm was so rigid and deformed by contraction as to make it well nigh useless, yet the patient persevered in making his business pay, entered prize competitions, etc. He took no sedatives. The motor, trophic, and circulatory defects remained unchanged. The character faults became less pronounced, although they are none the less present on excessive stress. To him his little farm is an object of admiration and continued engrossment. His epileptic retardation has disappeared and he says, "My work is my one salvation in the world."

The third case has by no means been attended by so signal a therapeutic triumph, yet what may be done with long-standing organic lesions and their sequelæ of epileptiform fits is well illustrated here.

CASE III is that of a man now 57 years old, who has

been an epileptic since an attack of scarlet fever at ten years, following which he had a slight but enduring right hemiplegia. The patient made a poor sexual adjustment, and under social and economic stress he became a grand mal epileptic. As deterioration advanced he became more and more engrossed in his past domestic and economic failures, including a sexual impotence. A series of attacks was precipitated and encouraged by certain unconscious ideas formulated under an exaggerated potency and homosexual trend. Finally there were crude infantile ideas of divine impregnation and childbirth, or his own rebirth. Later he underwent the agony of crucifixion and the ascent to heaven as a final salvation from all his troubles. When the delirious episodes cleared the homosexual gift was transferred into a fund provided to save him and certain "epileptic children." As a last stage the institution was the thing really wrong and certain wise and beneficent individuals were to remake and reform the whole colony environment and thus make reality endurable for such unfortunates as himself—a wish phantasy ever present in the unadjusted epileptic. In mal adjusted and deteriorated cases such as the foregoing one can give little therapeutic aid, yet much may still be undertaken in the free periods between seizures to bring about a certain degree of insight by simple explanatory talks on social and sexual adjustments. A wise, friendly guidance may still direct such individuals to a happier interned life in an institution. The result of painstaking analysis and good advices for this patient has resulted in periods of physical and mental freedom from attacks and deliria twice as long as formerly. He has finally taken up useful work at the colony with actual interest and personal profit. Of course the organic lesion is not altered, but neither has it been altered in any of the spasmodic disorders earlier considered, yet the epiphenomena of the attacks and an irritable and a social attitude have been reduced to the minimum, and the sum total of personal comfort and happiness possible for such a patient has been greatly augmented. Even though the improvement should be temporary only, for a few years at best, the therapeutic endeavor is worth while. The gain in diagnostic value of the state is alone worthy of the effort.

It is extremely difficult to say just what induces epilepsy in these hemiplegic cases. It is not the location or extent of the structural lesion, for the former is exceeded in porencephaly or entire atrophy of one cerebral hemisphere. In double palsies or diplegias the extent of the lesion is greater, yet they are infrequently followed by epileptiform attacks, and when they do occur they are not uncommonly recovered from. I think it safe to say that epileptiform attacks invariably follow in every case of infantile hemiplegia. The epiphenomena of fits occur from a few months to several years after the original insult. In a material of several hundred cases the longest time the spasmodic attacks have delayed their occurrence was not more than six years. So the imminence of remote attacks after supposed infantile palsy "without palsy" should not be charged to organic mischief unless the onset of fits is close to the supposed cerebral injury. This principle holds true independent of the nature and extent of the lesions present.

What rôle, therefore, can the underlying lesion be playing through the epileptiform attacks? Obviously such cases are not similar in nature to essential epilepsy except that both may have somewhat similar convulsive phenomena; but the makeup in not a few of the hemiplegic epileptics would seem to make an enduring epilepsy take on the characters which the essential type so exquisitely expresses. Here again, with more reason, the neural imbalance

theory works with more show of material defense. It has been shown that a subsequent lesion on the unaffected side converting the case to one of double hemiplegia, causes the epileptiform attacks to disappear. The complete palsy of the damaged side as in a subsequent capular lesion of late apoplexy rids the former hemiplegic epileptic of his convulsive disorder. Singularly enough, with the riddance of the epilepsy the character mends and the psychic processes are bettered.

How does mental analysis and the training treatment improve those organic processes upon which the epileptiform attacks seemingly depend? One can only say, as in considering the tic disorder, that the removal of an untranquil psyche removes a continual disturbing factor and may reestablish an inhibitory control of no small moment. In brief, one may conclude this section with the statement that so long as we must look upon essential epilepsy as an organic or at least a constitutional disorder with certain mental attributes as the most outstanding diagnostic elements of the disease, we must place our emphasis of training and educational treatment upon the fundamental make-up rather than the convulsive part of the disease; and if we develop the epileptic as an individual within the healthful range of the possibilities of his egocentric nature we may so stabilize him to a healthy arrest from the more violent aspects of his epileptic reactions. This analytic plan of mental therapy is entirely compatible with the acceptance of an organic view of the disorder, whatever it may ultimately prove to be.

IV.—MIGRAINES AND NEURALGIAS.

True neuralgias and migraine, exclusive of the false types of hysteric or physical conversion symptoms, have a variantly construed neural and chemic pathology. Hardly anyone assumes other than a somatic basis for the true neuralgias in our pathology. Two illustrative cases of extraordinary moment may be given. The plan of treatment carries its own portent for the similar treatment of such diseases in future. It would seem that the question to be solved here is not by what method can a patient so afflicted be induced to exhibit increased fortitude in bearing pain, but rather how much of a given neuralgic disorder may properly be charged to the lesion or somatic state and what part of it is due to an excessive accompanying emotion known as an affect. Even though the latter be great, one must still reckon how much of it may be suppressed or borne without harm, and how much, though it be borne, seems to hasten the physical process underlying the neuralgia. Of course only in extreme or desperate cases should the great pains which we shall here illustrate be undertaken. The first case was not treated by analysis as a curative agent for the migraine as such, but only incidentally, for a supposed epilepsy found to be only a psychoneurosis, a convulsive pantomime of a supposed affect occurring at the mother's sudden death. The migraine was not a part of the psychic syndrome which first came under treatment as it had endured since early life and had hereditary cause and characteristics. In the absence of an hysteric character the condition might in all reasonableness be considered a true

migraine. Simple frontal headache did, however, play an important but nevertheless a secondary rôle in the psychoneurotic syndrome, and was due as a part of an unexpressed affect, a psychic determinant forcing for expression. In brief, the case is as follows:

CASE I is that of a man of thirty-nine. There was a history of attacks of migraine in the mother, a sister, and a paternal uncle. The personal history was negative aside from periodic attacks of migraine every month or so from earliest years. They were the usual sort, largely confined to the left side of the head, attended with photophobia and vomiting. When his psychoneurosis broke out he also had headaches, but these were quite dissimilar in location and character from the classic migrainous episodes. He had led a sedentary life as an expert bookkeeper; this, in addition to excessive indiscretions in diet, often provoked the migraine. The attacks were so severe that our patient suffered prostration in bed for a day or more. They were frequently aborted by morphine. Mental analysis for the hysteric repression which had simulated epilepsy resulted in a complete cure of the neurosis; the migrainous episodes also completely disappeared and have been entirely absent for over five years. The patient has not changed his occupation or daily habits.

Visceral neuralgias of a persistent and intensive character, especially in the genitocrural region, are rare. I have seen but two cases. My first was a middle-aged man who had attacks of pain in the left testicle, which endured more or less persistently for twelve years. It had all the clinical characteristics of tic douloureux. He was a man of character and prominence, and endured the state with the extreme fortitude characteristic of such sufferers. The neuralgia was without any hysteric stigma and defied all plans of treatment, and so far as I know it may still persist; he disappeared from my observation some years ago. The present case is interesting inasmuch as the pain, while no doubt of a true organic origin, was so out of seeming proportion to the actual condition that the mental state threatened to end in suicide. In other words, the affect generated by the pain was so severe as to seriously cripple the patient's mental usefulness. A combination of physical and mental therapy was successful. The case is as follows:

CASE II is that of a girl of nineteen who had her first attack of neuralgic pain in the vagina at eight years. They came on suddenly and lasted a few hours, then disappeared. In the interval she enjoyed perfect health. The family history was negative except the mother had migraine from early life until the climacteric. Our patient presented no physical disorder throughout her youth except these peculiar neuralgic attacks, which appeared at irregular intervals. At one time it was thought they were associated with a separative foal in a diverticulum in the bladder; later this did not prove true. Soon after a completely negative physical examination I saw her in an attack of pain and was at once impressed that the mental effect of the episode seemed enormously out of proportion to the probable amount of pain experienced. The patient, without perceptible alteration of the pulse, respiration, or temperature, showed profound depression and anxious states. She thought this illness would cripple her career at college, her future marriage, etc. Psychoanalysis was undertaken for this exaggerated attitude. Her fundamental emotional defect was the very marked repression begun in the first pain period. The infantile reaction remained even in adulthood. After several months' treatment there are now only the faintest traces of "discomfort," but no "real pain." Our patient has since happily married and is in excellent general health. The physical basis for the neu-

ralgic episodes themselves has apparently developed on the hereditary basis of such disorders plus pyorrhea, the teeth having been diseased from earliest life. The final removal of the latter difficulty has apparently reduced the possibility of the neuralgic attacks in any form.

In both cases one sees, perhaps, an enduring slight constitutional tendency still to the neuralgic disorder, but no doubt the disabling and crippling element is removed from both. Nor do the good results in the psychic treatment of constitutional and functional disease of the nervous system end here.

Many psychoanalysts have indirectly reported the favorable influence of mental therapy upon the physical disorder present in their psychoneurotic patients. It is sometimes hard for their critics to believe that such therapists have reported aright upon the physical betterments thus brought about. It is rather astonishing that the results have not been given more attention and credence by the internist. Jelliffe has reported in circumstantial detail the longevity and improvement by such mental therapy in a woman who had advanced renal disease. The rather marvelous results (not yet published) are worthy of intensive inquiry. Of course no one may hope that Bright's disease can be cured by such treatment, but that the patient is comparatively well and able to undertake his life work and activities alone makes the effort of amelioration worth while. Who may estimate the degree of physical harm advanced arteriosclerosis may sustain by the undue shunting of intensive affective impulses upon an already overburdened visceral disease? A case from many illustrating this point may be briefly cited in that of a man in middle life whom I gave psychoanalysis for homosexuality, not with the promise or even hope to render him heterosexual but with the purpose to make clearer and more convincing the different avenues of sublimation for these unfortunate perverse emotional impulses. The object of the treatment has been fairly well attained; just how this was brought about does not immediately concern us. At the beginning of treatment it was found that he had a fairly well-advanced arteriosclerosis; cardiac and nephritic crises were present every week or so. Arterial tension was high and gastric episodes were common. A year after treatment his nephritis has become quiescent, the anginal attacks have disappeared, his digestive attacks are removed, and his registered arterial tension has fallen thirty or forty points. The organic lesions are probably present though quiescent, and the whole organism has established a compensatory balance that permits our patient to lead a happy normal existence. Such instances, which are innumerable, must give the keen internist pause, asking himself whether or not there be a psychic component in his organic cases and whether it would not be wise to combine psychic therapy with his well-formulated physiotherapy. In taking such an attitude well within the domain of rational medicine we may curtail much of the specious quackery in the world to-day and enhance the value of a broader system of therapeutics for scientific medicine.

While from the very first beginnings of the new psychology some desultory studies have been in process, not until the last few years have we had a more or less systematic approach of its application

to obvious organic disorders of the viscera, such as lung and heart diseases. Furthermore, Campbell⁶ has called special attention to the rôle which the emotions, instincts, and personality play in these affections. While our knowledge has been enlarged through recognition that the activity of the thyroid in exophthalmic goiter influences the heart action, we find even in uncomplicated cardiac disease the vaguer but none the less insistent neurotic symptoms play a definite rôle. Thus morbid anxiety and ill adjustments of the sex life modify the course of cardiac disease. In asthmatic attacks and gastrointestinal disorders there are feelings of inferiority either innate or acquired which aggravate the essential inferior mechanism of the heart as such. The reverse is also true. An inferior heart may increase the feelings of inferiority of the personality as a whole, as Adler⁷ has contended. When combining these two possible interacting factors a study of any cardiac affection may be made much more comprehensible. As Campbell points out, to understand the relative values of psychic and somatic elements in causation of a heart disease requires experience, an open mind, and a nice intuition in the individual problem.

Not a few have gone more boldly into these psychic factors in their relationship to physical disease. Thus Taplin⁸ considers asthma as remarkably amenable to mental therapy, and cites many actual cases thus treated. Perhaps he has overstressed the essential psychogeny of these respiratory disorders which he has bettered. He may have included some cases not of the true asthmatic type, but his work and its report is a good augury for future therapy of these stubborn respiratory affects. Even in Mènière's disease he claims to have achieved good results by mental therapy. Taplin unfortunately has limited his form of mental therapy to that of suggestion. The relative importance of psychologic and physiologic factors in inducing physical disorders is discussed at considerable length by Hart, who calls attention to the fact that when we employ psychologic means in treatment to-day we may do so with quite as scientific accuracy as those embracing physiotherapy. The internist as a really effective therapist must be able to evaluate the one as carefully as the other, and a proper combination of both in the particular case should be his aim.

For a long time the internists' treatment of the tuberculous has stressed the prognosis, other things being equal, upon the mental and moral attitude of the patient rather than on the degree and extent of the lesion. Of late distinct therapeutic approaches have been formulated on those lines. Wilkes⁹ states the issues fairly. Of course psychic treatment even as physiotherapy cannot hope to actually restore lost tissue, but mental therapy may help one to remove the depressive emotional conditions, and establish instead a contented and optimistic state of mind, and thus actually improve the physiologic action of the viscera supplied by the sympathetic system, and indirectly stimulate general metabolism. In a study upon actual case material Ishigami¹⁰ found psychic acts frequently influence the tuberculous unfavorably; there were actual lowering of the opsonic index and transient glycosuria, and under exciting states increased ad-

renalin in the blood and diminished phagocytosis obtained. Miner⁹ is even bolder in asserting that mental therapy is of equal importance in tuberculosis treatment as physiotherapy. His views on the subject are none the less important though they are confined to conscious explanatory talks. He gives an extensive system of procedure. As regards mental therapy in systemic disease, claims of the many beneficial effects are cited by Rabinovitch;¹¹ thus Morat, the physiologist, and Walthard, the gynecologist, have shown such clinical results, while Dide and Witry have separately demonstrated the psychogenic motivation cure of certain forms of acute edema. Vogt produced pemphigus blebs by suggestion, and in the converse Jelliffe¹² by more comprehensive methods of mental therapy as psychoanalysis cured psoriasis. In conjunction with Evans, Jelliffe¹³ believed that the depressing effects of the inhibited emotions upon physiologic activity have been well established. They hold that the physician should endeavor to reestablish normal metabolic changes through psychic control. This may be brought about by relieving many patients of the great drain on their nervous energy through making known to them the unconscious conflict between the heretofore infantile wishes and the demands of the unconscious life. Work based upon concrete material is that of Adler, who through mental analysis of a case of trigeminal neuralgia which previously had been resistant to all forms of physiotherapy, yielded promptly to mental therapy. While Adler would not infer that all trigeminal neuralgias are psychogenic, he believes that given the proper condition the unconscious may seize upon these symptoms and increase or precipitate the neuralgic attacks for its own ends. Again analyzing so stubborn a physical disorder of the spinal cord as muscular atrophy, hypotonia, mechanical hyperexcitability of muscles associated with slowness of contraction, increased reflexes, sensory and vasomotor phenomena, Babinski and Froment¹⁴ insist that such are not entirely the result of immobilization, and hold that they are disorders partly reflex as well as psychic in origin. They find a combination treatment of physical as well as mental means gives best results.

We must conclude from some of the foregoing views it is not difficult to comprehend that the aggressive attitude of many physicians, especially those best equipped with the more recent and exact methods of psychotherapy, are invading the field of internal medicine both in studies of the causation of visceral and organic disease as well as in the application of exact mental therapy to bring about more hopeful results. It is obviously not the intention of such workers to urge a psychogeny for such affections with undue zeal but they sanely hold that the psychic factors in organic disease have been given too little attention in the past and that their claims for a mental therapy based upon such findings demand our most serious attention. Time and more exact control studies will make clearer whether the disordered psyche's continued assaults of a visceral organ which may possess an inferior mechanism may not be a potent factor in inducing disease in that organ.

Of comparatively recent years a broader and more comprehensive extension of the idea is in evi-

dence no less than the expansion or extension of a veritable psychogenic theory for all sorts of visceral disease. In brief, it is held that the proper functioning of all bodily processes have psychic stimuli and control and that instances are not uncommon in which the disturbances of circulation, digestion and all secretory activities have been signally perverted by these psychic factors over a number of years until the final resistance to disease in those organs has been made easy and then seemingly through simple physical forces of one sort or another has induced the serious or fatal disease from which the person often succumbs. There is reason to think that ultimately incipient psychic as well as chemic causes will be considered the forerunners to all sorts of internal disorders of the heart, lungs, liver and kidneys. Even now, though to some the idea is seemingly fanciful and without definite proof, we have report of indubitable clinical material which augurs well for the fruition of this hypothesis.

In conclusion of our general thesis we may summarize that sufficient data are at hand to show that improved principles of pure mental therapy have already shown how all sorts of spasmodic disorders constitutional or functional in origin and many psychotic syndromes supposedly of analogous somatic basis may be radically helped or cured by such therapy. Further, various other visceral disorders may not only be cured or brought to a practical arrest by mental treatment but this whole psychic approach in general medicine bids fair to offer one of the best rational explanations of some organic disease. By due heed and caution in the earliest application of mental therapy the method may offer one of the greatest advances to preventive medicine of recent times.

CLINICAL SYPHILIS OF THE CENTRAL NERVOUS SYSTEM.*

A PRELIMINARY STUDY.

BY JUNIUS W. STEPHENSON, M.D..

NEW YORK.

IN 1914, after an investigation of three years, I read before the New York Neurological Society a paper entitled "The Intensive Treatment of Syphilis of the Central Nervous System by Neosalvarsan Intravenously and Mercury by Inunctions." I then began a study of why certain cases improved and others did not. I soon learned that lues attacking the nervous system produced symptoms predominantly either cerebral or spinal. Continued study convinced me that lues rarely attacked the nervous system *en masse*, but produced symptoms referable to a patch of meninges here or there, a blood vessel of comparatively insignificant caliber, or a tract in the spinal cord. Upon the knowledge of anatomy and physiology of the nervous system depend the conclusions at which I have arrived. I have furthermore concluded that the successful treatment depends upon proper discrimination as to what anatomical and physiological destruction is caused by the initial invasion, certain structures being unalterably attacked, whereas others are undoubtedly amenable to the proper treatment. Therefore, it is absolutely essential that cases amenable to treatment be recognized in their very incipency. By the time the average patient reaches a neurologist cases which have been amenable to treatment have progressed to a degree where they show permanent damage, and it is for this reason that I shall call attention to the "little things" which should prompt one to at least suspect syphilis.

It is a matter of fact that post mortems give us very little, if any, information as to the primary invasion of the nervous system by the spirochæta—individuals rarely dying of syphilis of the nervous system in its early stage. Therefore we must of necessity rely upon the known and undisputed anatomy and physiology of the central nervous system for any conclusions we may arrive at in regard to the initial attack. I advise you strongly not to attempt to indulge in disputes relative to the minute anatomy and physiology of the central nervous system—leave that to the anatomists and physiologists.

It is my belief that the majority of general practitioners are disinclined to keep themselves properly posted as to the anatomy and physiology of the nervous system, hence a brief consideration thereof will not be out of place here. My remarks will be for practical purposes only. For more detailed considerations you are referred to any recognized anatomy and physiology.

Anatomy and Physiology. Meninges Covering the Brain.—It must be borne in mind that the cranial nerves pierce the meninges, and I wish particularly to call your attention to the space between the cerebellum and the brain stem, in which any inflammatory condition of the meninges may produce cranial nerve involvement, especially the fifth, sixth, seventh and eighth cranial nerves. I wish also to impress upon you the relation of the optic nerve to the

meninges. Especial attention is directed to the blood supply of the cerebrum and cerebellum. The artery of cerebral hemorrhage (lenticular striate artery) gives off numerous branches, one to the frontal region (mental and motor speech area), one to the Rolandic area (highest motor power area), one to the post-central area (higher sensory areas for normal sensations, pain, temperature), and so backward to the sensory aphasic and visual areas. One should familiarize oneself with the posterior inferior cerebellar arteries.

Spinal Cord.—It must be borne in mind that both the anterior and the posterior roots pierce the meninges within the cord. The following tracts are of the most practical significance: (1) Anterior horn, lower motor neuron tract, disease of which produces flaccid paralysis, like that seen in infantile paralysis; (2) the pyramidal tracts, disease of which produces spasticity (stiffness); (3) the spinothalamic tract, disease of which produces alterations in the sensation of pain and temperature on the opposite side of the body from the lesion; (4) the posterior columns, disease of which produces loss of sensation of position, and alteration of the sense of touch, and hypotonus.

General Considerations.—There have been described by a pathologist, I think, of Baltimore, whose name I cannot now recall, two species of the *Spirochæta pallida*, one which he claimed produced syphilis of the skin and bones, the other of which attacked the central nervous system. I am inclined to believe that this was a correct assumption. My experience has been such that I am of the opinion that an individual having grave secondary symptoms is much less liable to central nervous syphilis than one who has just had mild secondary symptoms or only chance, probably due to the fact that the individual with grave symptoms has been more vigorously treated. I am also firmly of the opinion that atavism plays an important role in the development of syphilis of the central nervous system. I am furthermore of the opinion that any individual who has had syphilis with or without secondary lesions, for his protection, should have performed a lumbar puncture every two years between the ages of twenty-five and thirty-five years. Only recently a young man came to me for advice relative to marriage. He had had syphilis several years before and simply wanted to know if it were safe for him to marry. The man presented no subjective symptoms whatever, and the only abnormal objective finding was a very slight irregularity of the pupil. Lumbar puncture revealed a 4-plus Wassermann reaction, two hundred odd cells, an excess of globulin, and a colloidal gold luetic curve. I could quote others, but time would not permit.

Multiple pregnancies do not eliminate syphilis of the nervous system. The absence of conception is suspicious. No stratum of society is exempt.

The one criterion of syphilis of the nervous system is the pupil. We hear a lot about the Argyll-Robertson pupil, but I want to warn you that the Argyll-Robertson pupil does not develop over night, and when it is complete in its entity your patient has some permanent damage. Any irregularity of the pupil in an individual under the age of forty years, particularly if associated with slowness of light reaction and inequality of size, must of neces-

*Read before the Baltimore County Medical Society, May 26, 1920, and before the New York Neurological Society, October 5, 1920.

sity be considered luetic until proved otherwise. I wish to call your attention to what I have styled "dead man's pupil." This is a peculiar, dull-grayish look to the pupil. Experience is necessary to recognize this phenomenon. In the normal individual there is a haze to the pupil but, unlike the "dead man's pupil," this haze has a greenish hue. The haze in the "dead man's pupil" prompts one to suspect a cataract or corneal opacity; but unlike these two, by use of the ophthalmoscope one can see through the hue of the "dead man's pupil."

Aortitis is a frequent accompaniment of central nervous syphilis. In cerebral vascular syphilis ophthalmoscopic examination is often of vital corroborative service, revealing endarteritic changes manifested by a longitudinal white streak and by kinking of the retinal vessels, associated with a low blood pressure.

The colloidal gold reaction can no longer be considered pathognomonic of syphilis of the nervous system, inasmuch as it is frequently found in other neurological conditions. However, when present, with corroborative serological and clinical findings, it is of the utmost significance, inasmuch as it is the last of the various serological findings to respond to treatment and is therefore of valuable prognostic aid.

Syphilis Within the Cranium. Meningitis.—Syphilitic meningitis differs from the usual forms of meningitis in that it is more frequently associated with cranial nerve involvement and choked discs. (Of the cranial nerves involved those most frequently encountered are the optic nerve, fifth, sixth, seventh and eighth cranial nerves.) Less frequently do you find the profound illness and typical Kernig sign. The initial symptoms are usually local in character and in my experience have been most frequently referable to the frontal regions, next in frequency, the cerebellar pontine angle. The cranial nerve involvement with choked disc can probably be explained upon gumma formation. The serology here usually reveals, in addition to other positive findings, a high pleocytosis.

Isolated Gumma.—Isolated gumma of the brain produces all the usual findings of brain tumor, and differs from the gummatous meningitis only in the persistence of the isolation of its location and the serological findings which usually reveal a low pleocytosis.

Cerebral Vascular Syphilis.—This is the most frequent form of cerebral syphilis. I wish again to refer you to the anatomy of the lenticular striate artery. When any individual under the age of forty develops a sudden apoplectic stroke, the burden of proof that the condition is not luetic rests upon the examining physician. Unlike the apoplexies caused by nephritis and arteriosclerosis, those produced by syphilis, in the vast majority of cases, have had premonitory symptoms before the fatal onslaught antedating it anywhere from a few weeks to three or four months. Unfortunately these premonitory symptoms have been considered of no particular significance, treated as such mild maladies as "indigestion," and so forth. I quote the following cases: A patient appeared in the clinic six years ago complaining of headache; he showed a distinct speech defect, and the pupils were strongly suggestive of syphilis. He was told, as well as his wife,

that the probabilities were that he had a serious condition, but neither one of them was willing to accept it. He was strongly advised to enter the hospital for lumbar puncture and other investigations, but the family could not see the wisdom of this. Six weeks later I received a most urgent call and found the patient the victim of complete right hemiplegia with motor and sensory aphasia. Investigation proved the luetic nature of his malady. This man's speech defect was caused by the invasion of the branch of the lenticular striate artery which supplied the left frontal area. Another patient, sent to me because he had a 4-plus Wassermann, gave a history to the effect that three months previously he had had a spell in which he "lost his right arm" for a period of twenty or thirty minutes. This was a post-central manifestation and was due to the invasion of that branch of the lenticular striate artery which supplies the areas of the brain of the normal sensation. The only objective finding in this patient was irregular, unequal and sluggish pupils. The serology proved positive in toto. Before treatment was instituted he suffered an acute apoplectic stroke with both sensory and motor aphasia. Whereas, the logical assumption in that *a priori* the lenticular striate artery was diseased, the premonitory symptoms are directly attributable to thrombotic or absolute endarteritic changes in the smaller branches of the lenticular striate artery.

Thrombosis of the Posterior Inferior Cerebellar Artery.—I have seen three of these cases, two of which proved to be syphilitic, one alcoholic. The syphilitics improved to the extent that they could return to work. This condition is characterized by a sudden onset of giddiness, vomiting, and difficulty of deglutition and, in addition, paralysis of the fifth cranial nerve (inability to feel pin-prick on the face) and ataxia on the same side of the lesion, with a hemiplegia and a disturbance of the subjective sensations on the opposite side of the lesion.

General Paresis.—I have subdivided general paresis into two classes, namely, meningeal and parenchymatous. It is rare to-day that one sees in private practice or clinic work the genuine paretic which was seen ten years ago. The subdivision is dependent on the original onset of the disease. I believe that certain paretics begin primarily as a meningitis and by a continuity of tissue become the real confirmed paretic. The meningeal paretic is primarily a meningitis of the frontal area and the paretic symptoms are simply those due to irritation concomitant with the propinquity of tissue. The meningeal paretic will complain of headache; he will have insight into his condition, there will be less deterioration, and although he will have tremor of his tongue and of his lips they will be more or less gross and not be the fine fibrillations observed in the genuine paretic. He will not have the omissions in writing, nor will he present the grandiosity or the careless habits of the parenchymatous paretic. The serological investigations will reveal the meningitis paretic to have a high pleocytosis, a less persistent Wassermann reaction, and globulin content. He may or may not show the alleged typical gold colloid curve of the parenchymatous paretic, meningeal paresis, prognosis favorable.

Syphilis of the Optic Nerve.—Any disease of the

optic nerve, of course, produces more or less disturbance of vision. Syphilis in attacking the optic nerve produces the symptoms in one of two ways—either by direct invasion of the optic nerve itself, or secondarily by invading the structures about the optic nerve. Unfortunately the most frequent attack is direct, and associated with *tabes dorsalis*. With direct invasion, the disturbance of vision comes on very gradually and often an individual is practically blind in one eye before he realizes that there is any trouble with his vision at all; and more frequently than otherwise it is by accident that the patient learns of his malady, some little incident in everyday life calling his attention to some defect in his vision. Pain is rarely if ever complained of. The condition here is a primary atrophy of the optic nerve. Indirect invasion of the optic nerve is a result of either periorbitis or meningitis in the location of the optic nerve. Pain is here a conspicuous symptom and the defect of vision is from the beginning a compression neuritis, but the process, continuing by continuity of tissue, becomes an inflammatory process—similar to the involvement of the posterior root of the spinal cord in “meningeal *tabes*,” a description of which follows. The optic nerve is also indirectly involved in gummatous meningitis and isolated gumma of the brain associated with choked discs, the condition produced being dependent upon the general increase in intracranial pressure, the final outcome of which, if not relieved, being a post-neuritic atrophy.

Syphilis of the Spinal Cord. Tabes Dorsalis.—Before the advent of serology the French school taught that the initial lesion in *tabes dorsalis* is a posterior meningitis of the spinal cord. Oppenheim and others did not agree, but considered the initial lesion a neuritis of the posterior roots or a posterior ganglionitis. It is a well-known fact that direct invasion of the posterior column of the spinal cord is rare. My experience has convinced me that both the French schools and Oppenheim and his followers were in part right. The fact is that given any large clinic one can readily classify his cases according to the teaching of these two schools, therefore I have subdivided *tabetics* into two classes, namely, meningeal and parenchymatous *tabes*, depending upon the initial pathological onset. The clinical symptoms presented are as follows: Meningeal; the principal symptom here is pain. The patient comes to you because he has pain, described as boring, burning, shooting, and so forth. In addition, he may tell you that he has occasionally awakened from his sleep by a sharp pain causing his leg “to jump up.” Ataxia is conspicuous by its absence, as are also sexual disturbances. This man will not have the typical Argyll-Robertson pupil, but will have an irregularity, an inequality, or some slowness of light reaction. Also, there will be some evidence of the “dead man’s pupil.” His deep reflexes in the very early stages will be present and if anything over-active. As the disease progresses his reflexes will become altered, the first of which to be affected being the ankle jerks. A peculiar phenomenon which is present in the vast majority of these meningeal cases is a diminution or absence of the deep muscle pain sense in the calf muscles. In eliciting this it must be recalled that the superficial sense is usually acute in these meningeal cases and

that at first the patient will experience pain while upon continued deep pressure the superficial sense will be overcome and the phenomena above mentioned elicited. My usual method of eliciting this symptom is to grasp the calf muscles firmly between the thumb on one side and the fingers on the other, slowly but progressively increasing the pressure. In normal individuals when thoroughly relaxed this is very painful. Caution must be exercised that the patient is relaxed. Given any case of so-called rheumatism or neuritis without definite physical findings, my advice is to squeeze his calf muscles and if, in doing so, you do not cause pain then do a lumbar puncture and Wassermann and assure yourself that you are not dealing with meningeal *tabes*. These patients represent the preataxic or pain-stage of *tabes dorsalis* as outlined in the average textbook, and in view of the fact that ataxia is conspicuous by its absence, the use of the term locomotor ataxia is not only misleading, but has resulted in many of these cases going unrecognized until they have become parenchymatous *tabes*. The lesion here is a posterior meningitis, and the pains are caused by an infringement upon the posterior roots as they pierce the meninges; and you can readily understand that a continuance of the inflammatory process will involve the root itself, later extending up to the posterior ganglion, and so on to the posterior column, giving the classical picture of *tabes dorsalis*.

The loss of the deep muscle pain sense in these cases, I believe, is *per se* a posterior root phenomenon, this sensation being conveyed by certain selective fibers yet to be demonstrated. In corroboration of this, given a case of subacute combined sclerosis in which we know that the posterior columns of the spinal column are involved and which do not give posterior root symptoms, this phenomenon cannot be elicited. Meningeal *tabes*, prognosis favorable.

Parenchymatous Tabes.—These patients come not so much for pain but because they “can’t walk well” or have some sexual disturbance; or, maybe, on account of defective vision. In addition, sphincter troubles will be in evidence; in fact, they present the classical findings of a well-developed case of what is to-day looked upon as *tabes dorsalis*. Here you find your Argyll-Robertson pupil, absent knee and ankle jerks, and other classical findings. The serology of the two conditions varies: the meningeal giving you a high pleocytosis, above 80 cells per cubic millimeter, limited excess of globulin; the parenchymatous showing a low pleocytosis and a marked excess of globulin, both of course showing a positive Wassermann reaction, the meningeal being less profound.

Syphilis of the Anterior Horn.—This condition was first described by Dana some ten or twelve years ago. The condition was considered an endarteritis. It is of rare occurrence, but is one of those most amenable to treatment. It usually occurs in individuals between twenty-five and thirty years of age. The symptomatology is quite typical, being as follows: Pain is inconspicuous, though there may be experienced a sensation of pain for the first few days, after which a sensation of numbness or deadness is complained of in the affected limb. This is followed by a motor weakness and in

course of time the patient "accidentally" notices that the hand or part involved is "shrivelling up." The peculiarity about this invasion is that the disease attacks a certain segment for a while, then attacks another. For example, it may attack the segments supplying the hand muscle, where it will progress for a period of six weeks or three months, when it becomes quiescent; then it will attack another segment, for example, the shoulder, and progress likewise, and if not recognized will continue to attack individual segments in this order.

There is also a chronic endarteritis of the anterior horn, the course of which is similar to a progressive muscular atrophy, the distinctive features of differentiation being that in the luetic chronic endarteritis of the anterior horns motor weakness precedes muscle atrophy, and the progress is much more rapid. This condition develops after the age of forty. The serological findings in the subacute form, if recognized in its incipency, that is, during the few days of pain, will show a high pleocytosis; otherwise both conditions reveal a few pleocytosis.

Anterior Column and Pyramidal Tracts.—This condition is usually observed in individuals between twenty-five and thirty-five years of age, and is characterized by a fairly acute onset, drop-wrist or drop-foot, associated with pyramidal findings such as the Babinski phenomenon, clonus, and absent abdominal reflexes. Motor weakness is profound, but distinct atrophies in the early stage are rarely encountered. Pain is insignificant, but preceding the motor weakness, paresthesia, such as numbness, deadness, are usually complained of. Urinary incontinence or precipitancy is at times a distressing symptom. The condition bears a close similarity to multiple sclerosis but, unlike multiple sclerosis, the profoundness of the symptoms in this condition is due to the lower motor neuron tract involvement and not to the pyramidal tract. Also, unlike multiple sclerosis, this condition shows the pupillary phenomena and serological findings of syphilis. The condition is very amenable to treatment. A condition somewhat analogous to this has been described by Spiller.

Pyramidal Tracts Alone.—This is, in reality, the condition described by Erb as Erb's syphilitic spinal paralysis, and is a degenerative process. The onset is usually between the ages of twenty-five and thirty-five and the malady is characterized by a progressive spastic paraplegia with more or less sphincter and sexual involvement. Pain is inconspicuous but various paresthesias may be present. The usual complaint is that the legs feel stiff. At the height of the lesion there can often be demonstrated a zone of hyperesthesia. The serological findings usually reveal a low pleocytosis. Prognosis unfavorable.

Transverse Myelitis.—The symptoms here observed are those of any acute transverse myelitis. The condition is amenable to treatment but unfortunately the flaccid paralysis of the onset is usually supplanted by a spastic paralysis which no amount of treatment can overcome.

Pachymeningitis.—Localized pachymeningitis may occur anywhere, but in my experience the most frequent location has been the sacro-lumbar region, giving rise to symptoms which are often incorrectly diagnosed as sciatica. Sciatica, *per se*, like hysteria,

is a dangerous diagnosis, and the burden of proof upon the examiner is to prove that the condition is not sciatica. Pachymeningitis in any location is characterized by pain, motor and sensory phenomenon. In the lumbar-sacral region the symptoms are, pain in the back for a period of a few days, later extending down the thigh and legs, usually on the posterior aspect. As the condition progresses, there will ensue atrophy of the thigh and leg muscles with diminution or abolition of the deep reflexes, and it must be borne in mind that, unlike sciatica, the knee-jerk will be affected. Lumbar puncture will of course clear up any doubt and in early stages reveal a high pleocytosis. Prognosis favorable.

Peripheral Nerves.—It is my experience that peripheral nerves are rarely attacked by syphilis and that of those attacked the external popliteal has been the most frequent. There have been observed a number of cases presenting a typical seventh cranial nerve palsy, which showed a persistent positive blood Wassermann, but negative spinal fluid serology. Some have and some have not improved under antiluetic treatment but the clinical course has been so identical with that of the usual seventh nerve palsy that I am at a loss to know whether or not syphilis is an etiological factor in the development of isolated facial paralysis. Many cases of typical trigeminal neuralgia with positive blood reactions have been actively treated, but with no relief of their symptoms. Isolated ptosis, recurrent, is usually of luetic origin and responds to treatment.

20 WEST FIFTIETH STREET.

THE DIAGNOSIS OF STOMACH CONDITIONS.

BY CHARLES FRANK MORSMAN, M.D.,

SPOKANE, WASH.

IN arriving at a diagnosis in those who come to us for stomach trouble, it is necessary to follow out five procedures: history taking, physical examination, laboratory tests, Roentgenoscopy, and Roentgenography. It is obvious that one may not depend upon a single clinical or laboratory fact in making a satisfactory diagnosis. The more findings one has, the more nearly correct is one's judgment, since one must have a complete picture of the problem at hand or fail most miserably at times.

Symptoms which are so often misleading may be checked by laboratory findings; Roentgenoscopic findings may be checked by Roentgenographic findings; and they in turn may be checked against symptomatic statements and laboratory results, and thus is built up a complete and strong outline upon which to base judgment and so render the painstaking physician less likely to be in error in diagnosis, prognosis, and treatment.

It is well known that many of those who come for aid in what they call stomach trouble or pain in the stomach, are in reality suffering from some other condition. The pain which they call stomach pain may be produced by the gall-bladder, the appendix, stone in the kidney or ureter, tabes dorsalis, angina pectoris, or be the result of some general condition such as arteriosclerosis. Since this is true, it is necessary to take a very careful history

and make a very careful and complete examination in every case with which one has to do, in order that there may be no unwarranted diagnoses.

It is well to have a carefully planned routine for taking all histories. In order that one may arrive at the gist of the matter at once, one may inquire of the patient what he considers his chief complaint; is it pain and where; or does he experience shortness of breath; or in fact just what complaint brings him for relief? In the family history one may inquire into the illnesses and habits of the family; did any die in infancy or early youth, and of what illnesses; is there a history of alcoholism, of tuberculosis, or of syphilis? The family history will often throw a great deal of light upon obscure cases of stomach disease.

The personal history includes a résumé of the patient's past life and the symptomatology of the case. Many who come for relief will have very indefinite and fanciful symptoms, since many of our patients have most erroneous ideas of human anatomy, and absurd conceptions of functions. Probably the best plan is to allow the patient to outline his symptoms and then by judicious questioning to bring out the salient points. When did the first symptoms appear; what was his occupation at the time; was it necessary to change his occupation, and when; or has it been necessary to give up all work; what relation does his distress have to meals, to exercise, and to sleep? Has he vomited, and the character of the vomitus; especially, did he vomit blood and did the vomitus contain food he had eaten six hours or more before vomiting occurred? Has he lost or gained weight; is he constipated or not, and has he passed tarry stools? It is best to go into the subject of pain very carefully; is the pain severe or mild or merely an uncomfortable sensation; is it continuous or paroxysmal; is it sharp or dull, lancinating or boring in type; where is its greatest intensity, does it radiate and where, what relation, if any, does it bear to the ingestion of food?

Physical examination, as in the history taking, should be carried out in a routine way. The following plan has been found convenient. Physical appearance: does the patient appear to be ill; is he well nourished or emaciated? Weight: does it bear the proper relation to his height; has it changed, and how much? Skin: is it soft, moist and pliable, or dry and rough; are the nails brittle; is the hair abundant or scanty, fine or coarse; are the mucous membranes anemic? The teeth should be examined; those missing and carious ones as well as the presence of pyorrhea should be noted. Is the tongue dry or moist, and is it protruded in the median line; is the throat normal and can pus be expressed from the tonsils? In examining the eyes one should note inequality of pupils and their response to light and accommodation.

The lungs should be examined carefully by percussion and auscultation. The heart should be outlined by percussion and auscultated for abnormal sounds and arrhythmia, and the sphygmographic readings should be taken. In going over the abdomen use one finger only in eliciting points of tenderness; feel the liver edge, the spleen, and if possible the kidneys. And finally endeavor to obtain reflexes and especially bring out the presence or absence of Romberg's sign.

Laboratory tests: the Wassermann is done in all cases. A recent writer says that syphilis may be the cause of the gastric disturbance; that it is generally admitted that five or six per cent. of ulcers of the stomach are syphilitic in origin, and that it has been suggested that ten per cent. is nearer the truth.¹

Uranalysis includes the specific gravity, tests for albumin and sugar, and the microscopic examination of centrifugalized sediment. If albumin is found, the blood must be examined for urea nitrogen and creatinine, and if sugar is found, examine the urine further for acetone and diacetic acid, and examine the blood for sugar and determine its carbon dioxide combining power. The examination of the gastric activity should be carried out in two procedures: first, by the motor meal, which consists of a bowl of well cooked rice and a tablespoonful of washed, uncooked currants taken with a glass of water an hour or more after an evening dinner of bread, meat, and potatoes. It is best to have the patient take this meal of rice and currants at nine o'clock in the evening, and present himself for the withdrawal of gastric contents at nine the next morning. After the patient has rested a few minutes the Ewald meal, which consists of a slice of bread without crust and four hundred c.c. of water, is given to him, and at the end of one hour this meal in turn is withdrawn and the two sent to the laboratory. The patient is now taken to the dark room and the Roentgenological examination is carried out.

The first or motor meal should, if the stomach is normal, give these findings: amount twenty to forty c.c., no food particles, total acidity of 15 to 30 degrees and free hydrochloric acid up to 10 degrees. If there is more than forty c.c. of fluid obtained, or if the total acidity is high, one may say that retention is present, which may be due to hypomotility as for instance, from cancer. If free hydrochloric is in excess, or if the amount obtained is less than twenty c.c. one may say that hypermotility is present and chronic gastritis or peptic ulcer may be suspected. Rehfuess and Hawk give figures which differ somewhat from those given in this paragraph.²

The second, or Ewald meal, should present these findings: total acidity sixty to eighty degrees, and if one wishes to read percentages of acidity it is only necessary to multiply the number of degrees by .00365, thus forty degrees equals .148 per cent. There should be no lactic acid and the total acidity should bear a fairly definite relationship of three to two to the free hydrochloric acid. If there is a high total acidity and low free hydrochloric acid, it may be the result of organic acids, one of which is lactic acid, and may argue for carcinoma. So combined acids and organic acids and acid salts are always carefully computed.

The tests for occult blood have fallen somewhat into disrepute, since the tests are delicate and may be positive because of admixture of minute quantities of blood from wounds produced by the stomach tube or by retching, or by the meat eaten the evening before. Gastric ulcer, early gastritis, gastric dilatation and gastric neuroses produce hyperacidity. Hypoacidity is present in carcinoma, chronic gastritis, pernicious anemia, and in achylia gastrica there is an entire absence of acid.

In the writer's opinion, the internist should follow his gastrointestinal cases to the x-ray laboratory if he can possibly afford the time to do so. He certainly should be as conversant with the Roentgenologist's technic and terminology as he is with that of the physiologic chemist, the serologist, and the bacteriologist. The technic of examination by the Roentgen ray varies with different workers. The double meal as first described by Haudek and as later described by Carman and Miller¹ is now, variously modified, very generally used. The following is the technic employed by the last named authors: At the laboratory the patient is given four ounces of well cooked wheat breakfast food in which has been stirred two ounces of barium sulphate; according to his taste may be added milk, not cream, and a little sugar. He is asked to abstain from other food or drink, except water, until the examination is completed. He returns six hours later and is taken to the screen room. The chest is briefly inspected and next the position and distribution of the six hour meal is noted; then the patient is given a mixture of eight ounces of water and two ounces of barium sulphate, freshly stirred. While he is drinking this the canalization is observed. The patient is next given a mug of twelve ounces of cornstarch pap with barium. After the stomach has been carefully examined by means of the fluoroscope, plates are made as will be outlined in another method. These same authors say of the double meal:² "The principal advantage of the six hour meal is the saving of time to the examiner and of annoyance to the patient entailed by the repeated screening and plating."

The following method is employed by many able workers and probably is less liable to lead to difficulties: When the patient is sent into the dark room for the Roentgenological examination, he is asked to remove all clothing to the waist (a woman should be covered with a gown). He is first asked to step in front of the upright Roentgenoscope and the lungs and heart are examined and any abnormality noted. He is then handed a glass of four hundred c.c. capacity containing buttermilk in which is a heaping tablespoonful of barium sulphate, thoroughly mixed. He is asked to take a swallow of the mixture and the bolus is watched as it descends the esophagus and enters the stomach. It will be seen to hesitate at the aortic arch, and just before it enters the stomach at the cardia, and it requires from two to ten seconds for the bolus to travel the length of the esophagus. This procedure is for the purpose of ruling out cardiospasm, cancer, diverticula, and unusual contractions of the esophagus. Now the remainder of the mixture is swallowed and is watched as it enters the stomach and settles down into the lower pole; then a second glass of the mixture is given and after a short time, about five to ten minutes, usually, peristalsis will set up and the position and the motility are observed and an attempt is made to observe the duodenal cap. At least three plates are now made of the stomach and as a routine one plate of the gastrointestinal tract is made at the end of five hours and at the end of twenty-four hours, and sometimes at the end of forty-eight hours and at the end of seventy-two hours. This covers the technic of the Roentgenological exami-

nation of the esophagus, stomach and intestines, but one must also make complete Roentgenological studies of the renal system and the gall bladder in order to rule out diseases of these organs which may at times give rise to symptoms of stomach disease.

A prominent Roentgenologist says: "I have seen the futility of incomplete examination so often that I almost refuse to make an incomplete study. The great majority of patients sent to me for an examination of the 'stomach' because of stomach symptoms, do not have any lesion in the stomach but have disease of one of the other organs, most often of the gall-bladder or the appendix."

It is necessary to allow forty-eight hours for the Roentgen examination of the patient who presents himself for diagnosis, because of "stomach" symptoms, and it is often necessary to allow another twenty-four hours, especially if the results of the early examination point toward the appendix as being at fault.

From a Roentgen viewpoint of stomach symptoms, one considers stasis, incisura, niche, filling defects, spasticity, activity, and motility. The Roentgen ray has shown us the outlines of the normal stomach and that the position of the stomach, as taught to us who received our medical training fifteen or more years ago, was a misconception. When the writer was an undergraduate, our professors often marked out the stomach by percussion. We now know that they often outlined portions of the colon instead of the stomach. We know that a stomach which is normal to a short, thick individual is abnormal to the one who is tall and spare. There are two main types of stomachs, the steer horn type and the fish hook type, or as it is sometimes called, the "J"-type. The type which is normal to the individual is termed the orthotonic type. To classify according to Schlesinger, there are four varieties: the orthotonic, hypertonic, hypotonic, and the atonic.³

An orthotonic, adult stomach will accommodate eight hundred cubic centimeters very well. This will not fill a stomach of the hypotonic type, but by manipulation the outline may be nicely brought out. Because of these facts, one may use two glasses of four hundred cubic centimeters each of barium mixture as has been suggested.

Under the fluoroscope one notes the depth and rapidity of peristaltic waves. These waves, as seen under the fluoroscope, do not begin at the upper pole of the stomach, but lower down, about the beginning of the pars media and differ in individuals as to depth and rapidity of progression. However, observations by barioentgenography in which a dozen plates were exposed during the progress of one peristaltic wave, occupying on the average twenty-two seconds, after the ingestion of the bismuth meal, the wave was shown to begin at the incisura cardiaca and progress without bisecting the stomach at any point. A recent article tends to disprove the theory of Pawlow that the pyloric sphincter is under "acid control."^{4,5,6}

In the fluoroscopic examination of the stomach one notes the progress of the peristaltic wave or its absence, filling defects are observed, incisuras are noted, and the gastric outline carefully studied for niche and spasticities. Ninety-five per cent. of gastric cancers give Roentgen signs, and nearly

one-third of all cancers occur in the stomach.^{2b} Ninety-five per cent. of gastric tumors are cancer.^{1a}

Hyperperistalsis suggests either irritation or obstruction. Thus, in gastric ulcer there is a great likelihood of hypermotility. Reflex irritation, as from appendicitis, may show its presence by overactive peristalsis. Obstruction in the pylorus, as in old ulcer, may bring about the same result. Gastric cancer may give rise to either hyper- or hypoperistalsis, depending upon the extent of infiltration. Reverse peristalsis may be noted in gastric cancer. Hyperperistalsis may be the result of gall-bladder disease.

Incisuras may be due to ulcer, cancer, or reflex irritation. If reflex, the condition will probably not continue day after day, or may be ruled out by administration of belladonna. As a general rule, narrow incisuras indicate ulcer, while broad incisuras indicate cancer. Filling defects usually indicate new growth in the gastric wall; however, they may be the result of intragastric tumor, or due to food which is sometimes taken by patients against orders, or due to the presence of unusual material in the stomach, as for instance hair balls.

The niche is caused by ulcer. It was first described by Reiche in 1909, and further commented upon by Haudek in 1910. It is a bud-like projection showing on the outline of the stomach shadow, and is usually crescentic, but may be irregular in shape. It may occur in any part of the stomach but is usually seen along the lesser curvature. It is difficult to visualize at times, and then one must depend upon indirect signs for the diagnosis of ulcer.

All of the above signs will be seen by the aid of the fluoroscope and on the plates. Each method has its advantages, and it is always well to check one against the other. They should be balanced against laboratory findings. The symptoms are next taken into consideration. Finally, the case history is studied in the light of the other knowledge so tabulated. Thus is built a definite diagnostic structure upon a solid foundation of scientific facts which leaves no room for empiricism or conjecture.

TUBAL PREGNANCY, WITH REPORT OF A CASE.*

By JOHN W. WINSTON, M.D.,

NORFOLK, VA.

TUBAL pregnancy includes all forms of gestation that originate outside the uterine cavity. So far as known, all ectopic pregnancies, with the possible exception of a few ovarian, originate in the Fallopian tube. It is conceded that in at least a large proportion of cases, fertilization of the ovum occurs in the Fallopian tube. Spermatozoa have been found in the fimbriated extremity and it is probably here that they unite with the ovum.

The diameter of the unimpregnated ovum is not over two-tenths of a millimeter and that of the tube two to three millimeters. Tubal pregnancy occurs about once in each one hundred and twenty-five pregnancies.

The oviducts or Fallopian tubes, while they vary in form, are quite uniform in their histological structure throughout their whole extent. Continuous at the isthmus with the uterus, they open at the fimbriated extremities into the peritoneal cavity. The wall is divided into a mucosa, a submucosa, a muscularis and a serosa.

The mucosa consists of a well-developed fibrous membrane, rich in elastic fibres and well supplied with blood-vessels and lymphatics, which support a simple layer of columnar ciliated epithelium. An imperfectly developed muscularis mucosæ, consisting of longitudinal bundles of smooth fibers is also present. The mucosa is in longitudinal folds and secondary folds that are especially abundant in the ampulla and infundibulum. The inner surface of the fimbriæ is covered with the mucosa, the outer with the serosa. The submucosa is a simple layer of areolar tissue which contains small ganglia and multicellular cells which form a rudimentary plexus. The muscularis consists of an inner circular and outer longitudinal layer of smooth muscular fibers. The serosa consists of a thin fibrous membrane supporting the serous endothelium.

The ovum is propelled then by the wave motion of the ciliated columnar epithelium, the action of its elastic fibers, and the contraction of the smooth muscle fibers that respond to the call from the contained nervous plexus, possibly stimulated by the presence of a foreign body within the lumen of the tube. Anything that interferes with the mechanism of these parts tends to make it an element of luck if the ovum is conducted through to the uterus.

The predisposing causes are: (1) Inflammation of the tube, causing (a) destruction of the ciliated epithelium, leaving denuded patches which obstruct the ovum; (b) loss of the peristaltic action of the tube; (c) cicatricial contraction in the tube. (2) Long and tortuous tubes with small lumen. (3) New formations in and around the tube. (4) Torsion of the tube. (5) Diverticula in the tube. (6) Conditions giving rise to sterility of long standing.

It may be in that part of the tube that traverses the uterine wall and is thus called interstitial pregnancy. If the ovum is lodged in the middle por-

*Read before the Norfolk County Medical Society, December, 1920.

tion, the condition is called isthmic pregnancy. The most frequent form is when the ovum is lodged in the outer third, and is called ampullar pregnancy.

Developments that may take place are:

If in the ampulla, the ovum may be expelled into the abdominal cavity, this being called tubal abortion. The tube may rupture and partly or wholly discharge the ovum in one of four directions: (a) into the abdominal cavity, (b) into the space between the broad ligaments, (c) into space formed by adhesions between tube and ovary, (d) into the uterus. It may remain in the tube and die before maturity or go on to term.

Mrs. J. E. M., age 23, German descent. Puberty at 11 years—always painful on first day and last four days. First child born September 7, 1918, at the age of twenty—forceps delivery, perineum torn and repaired at time in hospital. Nursed child nine months and while nursing menstruated every three months. Became pregnant a second time when first child was nine months old. Abortion was produced by a catheter introduced at three months on September 15, 1919, and curetted the next day in New York. She did not notice any disordered menstruation after that, except that it would be delayed as much as twenty days often. In June, 1920, the patient had an attack of cystitis with pus in the urine, which cleared up after six bottles of lithia water.

Present illness—Menstruated September 21, 1920, for one week, which was normal in amount, but slight backache. Started to menstruate again after one week; the flow was small in amount and lasted seventeen days. Examination on October 9, 1920, showed the uterus tilted back, with no apparent enlargement of tubes or ovaries; but pressure on the right side against the finger was painful. At that time she complained of no pain in the abdomen or from defecation—only prolonged menstruation. On October 15, 1920, she had sudden pain in the right side, which was not described as in the pelvis, but coming from the back around the side to the inguinal region and passing down the right leg to the knee. This attack lasted ten hours and then disappeared for two days. There was no fainting or weak spell. The patient said there was pain on pressure over the right ovary. I was out of the city and a physician called in gave an anodyne and advised curettage, but did not make a vaginal examination. The patient said urination at that time was not painful, but caused a drawing sensation. There was no pain or discomfort on defecation.

These spells would disappear for a period of a few days and in the interim the patient would feel well. Each return would be ushered in by pain starting in the back, then passing to the side and around to the pelvis in front and down the leg. I saw the patient again October 22, 1920, when she was free from pain. On October 23, 1920, she was taken with considerable pain, which required morphine, gr. $\frac{1}{4}$, and atropine, gr. $\frac{1}{150}$. Examination showed no bleeding, but a small tender mass (size of a walnut) in the right side of the pelvis. Temperature was normal and pulse 80.

The woman entered hospital October 25, 1920. At that time the head, nose, throat, and teeth were in good condition; chest and heart normal and heart beat 80 per minute; temperature normal; blood count not made and blood pressure not taken. Skin clear, clean, and rosy in color; no glandular enlargements anywhere in the body. Fairly well nourished, but under weight. Abdomen negative to pressure except low down on the right side, where pressure gave pain. There was no anemia of lips or eyelids.

An x-ray examination showed two small stones in the region of the right ureter, one about the brim and the other at the level of the third lumbar vertebra, but they were irregular in contour and not in line with each other. Because of their irregularity, Dr. McGruder expressed the opinion that they were calcified plants. A shadowgraph catheter was passed by Dr. Harrell and both stones were shown to be outside the ureter. A specimen removed by the catheter was negative. An x-ray and catheterization of the ureter were both made

October 27, and that night the patient required two hypodermics and hot water bag for pain. Lumbosacral pain is often associated with inflammation around the tubes and ovaries, but pain in this location may be rheumatic, as the results of some focal infection in another part of the body, or, as the orthopedists tell us, it may be due to a looseness or straining of the ligaments that hold that joint.

The suffering in this case was not constant and was more painful than that we generally see in inflammatory conditions except when ruptures take place and local points of peritonitis are in the process of walling off.

Preoperative diagnosis: Small mass in the right pelvis. (I had a suspicion that an ectopic pregnancy was present, but did not have a conviction strong enough to put it in writing.) Endometritis, and cervix lacerated and ulcerated.

Operation: Examination under anesthesia showed a small mass on the right side with torn and ulcerated cervix. Perineum in good condition. Curettage and repair of the cervix were done and then a midline abdominal incision was made. On opening the abdomen a right ruptured tubal pregnancy was exposed to view, with a handful organized blood clot. A thickened and rather bad chronically inflamed appendix lay across the top of this mass and this was first removed and then the right tube and ovary with the organized blood clot. The left tube and ovary were brought up, examined, and found normal in every way. The uterus was very slightly congested, but there was practically no enlargement; its position was considered good. A small strip of iodoform gauze was passed through a rubber-tissue tube down to the site of the rupture to guard against oozing and wound closed. Drain removed on third day.

Because of ulcerated cervix a Wassermann test was made, but it was negative. Temperature on third day went to 105° F., due to irritation from catheterization of ureters. There was pus in the catheter specimen. Urotropin and water soon cleared this up and except for nausea for a few days recovery was uneventful.

330 STREET AND COLONIAL AVENUE.

Medicolegal Notes.

Proceedings on Review of Order of Medical Board.—On certiorari to annul an order of the California State Board of Medical Examiners revoking a license to practice medicine in the State, the court has nothing to do with conflicts of testimony before the board nor with irregular or erroneous rulings on admissions of evidence where the record shows that the jurisdictional requirements with respect to these matters have been fulfilled.—*Jordan v. Alderson* (Cal.), 192 Pac. 170.

Evidence of Other Illegal Prescriptions for Liquor by Accused Not Admissible.—In a prosecution of a physician for unlawfully issuing prescriptions for intoxicating liquor to be used otherwise than for medicinal purposes, in violation of Missouri Rev. St. 1909, section 5784, it was held prejudicial error to permit the State to introduce in evidence prescriptions other than those set out in the indictment, this evidence not tending directly to prove the particular crime charged.—*State v. White* (Mo.), 223 S. W. 683.

Proper Hypothetical Questions.—In a proceeding under the Workmen's Compensation Act for death alleged to have been caused by a blow, received in the course of employment, causing a rupture of the aorta, it was held that, though a hypothetical question to a medical witness might have been erroneous in asking for a speculative opinion as to what might have been the effect of the injury rather than the doctor's judgment as to what its effect really was, the error was cured where the doctor's answer showed that he thought he was being asked what, in his judgment, caused the aneurysm. It was also held that a hypothetical question to the medical expert based on the assumption that the deceased was afflicted with a preexisting aneurysm and received the blow as claimed, and asking the witness as to the effect of the blow in hastening the previous trouble, was not open to objection.—*Stewart & Co. v. Howell*, Maryland Court of Appeals, 110 Atl. 899.

RESECTION OF THE CERVICOTHORACIC SYMPATHETIC FOR ANGINA PECTORIS.

RESECTION of the cervicothoracic sympathetic was first performed by Jonnesco as far back as 1896 in the attempt to cure epilepsy and exophthalmic goiter. Later he tried out the intervention for glaucoma and migraine. Finally in 1916 he operated in the same fashion for angina pectoris. The case is unique in medical literature and the fact that the patient is alive and well today makes a report of unusual interest. The case was a typical one of angina pectoris and the operation performed was a unilateral resection of the left cervicothoracic sympathetic. In his examination of the patient exactly four years after intervention (April 4, 1920), the following facts were noted: The man continues absolutely free from any suggestion of his old malady and follows a double occupation in life as singer in a church choir and clerical work with success. His work, he says, makes it almost necessary for him to join in drinking occasionally with people, and his life is an irregular one and fatiguing; but even with this handicap he has had none of the symptoms which suggest a recurrence of his old malady. Three internist colleagues of the author examined the subject's heart and found the cardiac action, pulse, and respiration normal. The x-ray, however, showed plainly a slight dilatation of the aorta with irregularity of the wall and thickening of the same from atheromatous plaques, the individual thickenings or deposits being plainly in evidence and most marked at the beginning of the ascending aorta. The heart shadow showed a broadening of several centimeters with the apex a little low and to the left. Evidences of sympathetic resection persist in a narrowing of the left pupil and a slight narrowing of the palpebral fissure. (*La Presse Médicale*, March 9, 1921, xxix, 20.)

The history of the patient before operation is as follows: When first seen at the age of 38 he gave a history of syphilis, alcoholism, and nicotineism. The first access of angina had occurred on December 19, 1915, at 10 P. M., and the first visit to the author was made on March 19, 1916. Operation was performed on April 2 following. The patient

had had in all four crises of angina pectoris, and after the fourth announced himself as willing to submit to Jonnesco's operation. The Wassermann was positive and the x-ray shadows of the heart and aorta left no doubt as to the diagnosis. The author's operative method is of course well known to all surgeons. It is called by him "delicate but not difficult." It is done under the author's technique of stovainization of the spine, injection between the first and second dorsal vertebræ. Convalescence was smooth and the operation wound was healed in a week. The pulse before the operation had been from 44 to 52 and immediately after operation began to increase in frequency. By the third day it was 68 and apparently never exceeded 72 at any time afterward. The long lapse of time during which the patient was not seen was the consequence of the war. The result of this operation would seem to show that angina pectoris, despite its organic substratum, is essentially a neurosis and that by interrupting the reflex arc the condition may, sometimes at least, be completely arrested, the degenerated condition of the aorta being insufficient of itself to menace life immediately. The fact that Jonnesco chose the left side for the operation seems to have been due to the predominance of anginal symptoms on that side, the pain being usually reflected along the left arm. The author hopes that other surgeons will make trial of this operation. His patient was technically a very poor surgical risk, while many of the sufferers from angina pectoris are in comparison good risks.

THE PATHOLOGY OF DENTAL CYSTS.

WHEN fully formed, a dental cyst comprises a wall and fluid contents. The wall always has an inner epithelial lining, by the breaking down of which the fluid is formed, and an outer lining of fibrous tissue. The cyst is entire; there is never the bare dead end of a tooth root projecting into the cyst, but there is or has been invariably a septic tooth of the permanent set at the point of origin. In the fibrous wall of the smaller cysts a more or less extensive spongework of epithelium will always be found.

The earlier the cyst is examined and the smaller it is, the more abundant is this spongework, and the less conspicuous is the cystic cavity in relation to the whole of the morbid product. The liquid contents, which in the larger specimens are quite fluid and transparent, are found to be more tenacious in composition and to hold in suspension so large a quantity of cholesterol crystals as to give a superficial likeness to pus. This resemblance is further increased in the earlier phases by the fact that there is in the first formed fluid contents a certain amount of dead mesoblastic tissue and of inflammatory cells, as has recently been pointed out by Turner. Such small cysts are extremely common and are probably still referred to as abscess-sacs on account of the aspect of their contents. They are always found in connection with septic teeth of the permanent set.

The cyst may develop at any part of the root,

and a single tooth, especially multirooted, may present more than one cyst attached to it. If the sockets be examined after extraction, a small cyst will frequently be found which has been left behind, torn away from the root. Turner insists upon this fact and points out that the fully developed dental cyst is probably the commonest tumor of the body while the earliest stage of all is practically as common as are septic teeth. The earliest stage of a dental cyst consists of a spongework of epithelium; or in rare cases of a single bulb. This spongework of overgrown epithelium is almost always to be found in the inflamed and thickened alveolodental ligament surrounding septic teeth. It is included in a mass of interstitial granulation tissue, the result of a low grade chronic infection. Both granulation tissue and epithelial spongework are obviously the result of the same chronic inflammatory process. It is noteworthy that Turner, who has examined microscopically many hundred cases, found epithelium absent in only two instances and one of these was a large granulomatous bed surrounding pyorrheic lower molars, suggesting the possibility of sarcoma in its unusual extent.

Epithelial granulomata are very common in connection with septic teeth of both sets; small cysts are common in connection with septic teeth of the permanent set; fully developed cysts, clinically diagnosable, are not so frequent but still sufficiently so as to be probably the commonest neoplasm of the body; but they occur only with the permanent set. The reasons for this appear to be obvious. The temporary teeth, alveolus and its contents, are swept away before cysts have time to develop. Acute destructive inflammation and timely extraction account for the progressive diminution among permanent teeth.

Septic teeth have been spoken of instead of dead teeth, because though in fact the infection which culminates in a dental cyst is provided almost entirely by dead teeth, nevertheless the earliest stage—epithelial granuloma—is found commonly in the thickened alveolodental ligament of pyorrhea, and Turner has seen two instances of dental cyst in connection with living but pyorrheic teeth, and also a similar cyst of the gum at the point of exit of a chronic sinus connected with a dead tooth.

As to the actual infecting material, it is noteworthy that Turner has never succeeded in microscopically finding anything but yeast forms or in cultivating any other organism, but should there be any organisms present in dental cysts it is to be hoped that Drew's method of staining will enable us in the future to demonstrate them. Just now it would seem as if toxic infiltration were the effective cause. The histological picture of these granulomata—thickly aggregated plasma cells—is that always found in chronic infection of low virulence. When once started, the growth of the epithelium appears to go on independently of external stimulus after reaching a certain point. The originating tooth may be removed and the cyst still continue to develop, although no organism other

than yeast fungi—common in all inflammatory processes in the buccal cavity—have been demonstrated to exist.

PERSISTENCE OF PYLORIC AND DUODENAL ULCERS FOLLOWING SIMPLE CLOSURE OF AN ACUTE PERFORATION.

ACUTE perforation of a gastric or duodenal ulcer, with consequent soiling of the peritoneal cavity, severe pain, and shock, is a catastrophe which requires immediate surgical attention; for it has often been shown that in these cases, just as in cases of intussusception and acute intestinal obstruction from any cause, the mortality, in the hands of competent surgeons, varies directly in accordance with the amount of delay before operative treatment. In these acute cases the perforation takes place at or near the center of the ulcer, there may be much or little induration, extensive or very slight soiling of the peritoneum, and, depending upon the time which has elapsed and degree of peritoneal soiling, the patient may be in good or extremely poor condition. For these reasons the operator must vary his treatment to a certain extent, no matter what his opinion may be as to the proper steps to be taken in the average case. Some ulcers may be excised; some infolded, with or without cauterization; while in some cases closure of the perforation is possible only through the utilization of other structures, such as the omental transplant; also, the question of an immediate gastroenterostomy is to be considered. In the desperate cases closure of the perforation and drainage are all that may be advisable; but it must be remembered that simple closure does little or nothing toward curing the ulcer and that even though the patient may be so fortunate as never to have another perforation, his symptoms are likely to recur with their wonted regularity and there is the ever present danger of malignancy when the cancerous diathesis exists. Consequently, many surgeons believe that if the patient's condition does not present an absolute contraindication, gastroenterostomy, with or without pyloric exclusion, should also be performed. This would seem to be a logical conclusion; yet there is still a difference of opinion on this point.

Lewisohn, in an article appearing some time ago in the *Annals of Surgery*, emphasized the desirability of performing immediate gastroenterostomy in addition to handling the perforation itself, and cited four cases in which failure to perform gastroenterostomy at the original operation necessitated secondary operation for that purpose. He thinks we can safely say that operative recoveries are not impaired by an immediate gastroenterostomy and refers to Deaver's report of 25 cases where immediate gastroenterostomy was done with one death. In Lewisohn's own series of ten cases of acute perforation there was no mortality though immediate gastroenterostomy was performed in eight. Regarding the proposition that simple closure will usually fail to cure the ulcer, he says he

had occasion to observe four such cases in the short period of two years. In each of these the original operation consisted in simple closure of the perforation and drainage; and gastroenterostomy was required at periods varying from 10 months to eight years later.

Naturally, the individual surgeon's handling of these acute perforation cases should depend not only on the condition of the patient but also on the operator's ability to work rapidly. It is unquestionable that undue prolongation of operation time may turn the scale against the patient; but with the rapid operator, who works with the minimum of traumatization of the tissues, it would seem that, in the average case at least, the prospect of cure by immediate gastroenterostomy is well worth the added slight risk.

MICROORGANISMS AND SHOCK.

BAZY discusses this subject in the Surgical Number of *La Médecine* for October 20, 1920, ii, 1. The definition of shock by Piéchaud appears to answer the requirements of the French surgeons. Shock is a general condition more or less grave, characterized by feeble pulse, lowered pulse tension, pallor, insensitiveness and muscular weakness, with preservation of intelligence. The causes of this depressive syndrome are numerous, and without any attempt to enumerate them all the author isolates one which is the subject of the article—infection or the organisms which give rise to infection.

Shock, of course, may follow quickly upon traumatism alone, but there is a type in which infection plays a rôle. The germs include both pathogenics and saprophytes. The former is chiefly the streptococcus while the latter comprise the perfringens, the bacillus of edema, the septic vibrio and others. If the tissues have been badly contused an excellent culture medium has been provided. Multiplying at a rapid rate, they secrete toxin which can impregnate the organism much more rapidly than is ordinarily imagined. The presence of these organisms is usually apparent from the local reaction, but may be rapidly determined in advance by a bacteriological examination.

The condition under discussion, rare enough in times of peace, was prevalent during the war. It may still be of advantage in similar wounds of civil practice to continue the use of antgangrenous serum, making the injections simultaneously with those of antitetanic serum. The author further believes that in so-called operative shock with infected wounds the real motivation may be the bacterial toxins. This may occur in wounds in which time has been given to render them more operable. Thus in a case of appendicitis operation in the interval, death took place in twenty-four hours and could not have been attributed to operative shock.

In such cases there may be an element of bacterial anaphylaxis or microbial hypersensitiveness, so that the shock is of anaphylactic motivation. This phenomenon is well known, and whenever the

number of bacteria is insufficient to arouse an immunizing mechanism it is apt to sensitize the individual instead. These laws have been worked out in animal experiment. Operation on supposedly "cold" appendices can liberate bacteria and produce anaphylactic shock. The offender in these appendix cases is very often the *B. coli*, and the author suggests a prophylactic vaccination, or it may be better to try for an intradermic diagnostic reaction with the said bacillus. Should this prove negative the operator would feel much more free to intervene thoroughly, while if positive the operation might be contraindicated or at least the operator would be prepared for trouble, and would feel inclined to make use of the principle of anti-anaphylaxis before or just after operation.

RELATIVE FREQUENCY OF DENTAL CARIES IN THE TUBERCULOUS.

FARGIN-FAYOLLE, writing in *La Presse Médicale* for January 15, 1921, xxix, 5, refers to the articles on this subject of Paul Ferrier, who demonstrated in a classical manner the frequency of this association. He accounted for it by the demineralization to which the consumptive is subjected, which affects the teeth incidentally. Even in the pre-tuberculous period caries is often notable. Recently two theses have appeared on the same subject by Lemoine and Ferrier respectively, the latter being evidently a namesake of the original Ferrier, whose writings go back to 1900. Furthermore they in part antagonize the views of the older writer. They have instituted comparative researches on the tuberculous and controls in respect to the frequency of caries, taking subjects in the same general localities. Much care was taken in selection to eliminate sources of error. In the stomatological clinic of the Hotel Dieu, Paris, the percentage of caries and absence jointly was about 33 and in a strictly tuberculous service only slightly higher—35.22. The present author made some researches of his own. In the material of a surgical clinic the percentage of caries and absence was 20, in a medical clinic 28, and in a tuberculous service 33. A census of caries in average healthy subjects was not taken, but the incidence of caries in the tuberculous should be at least double the normal, which is computed at 15 per cent. Such low percentages of caries for French people will come as a surprise to the American reader, when he thinks of the 80 or 90 per cent. of caries in school children over most of the world, and he will wonder what may be the French criterion of a carious mouth. The author does not allude to any criterion nor is any mention made of filled teeth—whether a complete state of repair still means carious teeth.

NON-TUBERCULOUS COLD ABSCESSSES.

AUDAIN contributes an article on pseudotuberculosis of the cellular tissue to the *Gazette des Hôpitaux* for January 18-20, 1921, xciv, 6. The condition referred to appears to be relatively new. The clinical expression is cold abscess followed by fistulation. In such cases failure to find Koch's bacillus at first suggests some fungous infection, but in the cases

referred to the author has never found any evidence of mycosis. The culture and inoculation methods have invariably been negative. The age of selection seems anywhere from 15 to 40 and the author has seen many cases among the indigenous inhabitants of North Africa. While usually small—the size of an egg or mandarin orange—the author has seen abscesses which gave exit to a quart of pus. The physical appearance of the latter recalled a fungous infection, rather than tuberculous pus. Clinically it was impossible to exclude tuberculosis, and the fistula or ulcer formed after evacuation also resembled exactly that of tubercle. The golden hue of the pus was the only feature, aside from negative microscopic finds, to cause suspicion of the non-tuberculous nature of the process. The possibility of syphilis never even suggested itself seriously. The author recalled that cold abscesses have at times been traced to the staphylococcus, but this organism could not be accused in these cases. The condition responded well to the treatment of tuberculous cold abscess. The abscesses are often multiple and no very deep seated lesions have been seen, although the author believes that a case of empyema may have been of this character. It is possible, of course, that the tubercle bacillus or some undescribed fungus may have been responsible, even although all attempts to locate them repeatedly failed.

News of the Week.

Hospital News.—**NATIONAL HOSPITAL DAY.**—With the purpose of educating the public in the real functions of the 8000 hospitals in the United States and Canada, and focusing attention on the human side of the hospital, its varied services, its plants for expansion, and its needs, *Hospital Management* has selected May 12, the anniversary of the birth of Florence Nightingale, as the most fitting date for a National Hospital Day. All hospitals are invited to cooperate in celebrating the day. Each hospital will arrange its own program featuring its work and needs. The general direction of the day, however, will be under the control of the National Hospital Day Committee, 537 South Dearborn Street, Chicago. Sub-committees are being organized in the various States and in the provinces of Canada.

BILL TO AID COUNTY HOSPITALS.—The Pennsylvania State Department of Health is preparing a bill intended to aid counties in joining forces to build hospitals for communicable diseases. The Department of Health reports that there are 75,000 cases of tuberculosis in the State, and that probably 50,000 are receiving no care or attention. Private institutions and free sanatoria have less than 4000 beds, and but a fractional part of these are available for advanced cases.

NEW HOSPITAL FOR SOLDIERS' HOME.—The Indiana State Legislature has passed a bill appropriating \$225,000 for the erection of a new hospital and kitchen at the Indiana Soldiers' Home at Lafayette.

INFIRMARY FOR LIGONIER, IND.—Allen County, Indiana, is to have a new infirmary which will cost approximately \$750,000. The new institution will be located in Ligonier.

SITES OFFERED FOR GOVERNMENT HOSPITAL.—The Chamber of Commerce of El Paso, Tex., has been

offered free sites for the hospital to be built by the Government in one of the Southwestern States at a cost of about \$2,500,000.

TO REBUILD BILTMORE HOSPITAL.—Mrs. George W. Vanderbilt has offered a site of fifteen acres in the heart of the Biltmore estate, and a fund of \$25,000, to rebuild the Biltmore Hospital which was recently burned.

SANITARIUM IN JACKSONVILLE, FLA.—A sanitarium to cost \$20,000,000 is to be built on a 4000 acre tract of land near Jacksonville. The project is being financed by northern and eastern capitalists.

NEW WAYNESBORO HOSPITAL.—Construction work will be started soon on new \$145,000 hospital in Waynesboro, Pa.

COMMUNITY HOSPITAL FOR HUTCHINSON.—Articles of incorporation have been filed with the Secretary of State for a Community Hospital at Hutchinson, Minn.

THE RIVERSIDE HOSPITAL AT SAN JOAQUIN, CAL.—was recently destroyed by fire, with an estimated loss of \$50,000 to \$75,000.

THE BETH DAVID HOSPITAL, New York City, began a campaign, on April 1, to raise a fund of \$250,000 with which to complete and maintain an eight-story extension now in the process of construction. When the new building is completed the hospital will have four times its present capacity.

Bill to Save Small Medical Schools.—A bill was introduced into the Pennsylvania Legislature, on March 17, which has for its object to prevent so-called discrimination against medical schools not connected with universities. The measure amends the act creating a bureau of medical education and licensure of the Department of Public Instruction by providing that the rules of the board shall not provide for any different or higher standards for medical educational institutions than those provided for by the Pennsylvania statutes.

A New Degree in Medicine.—The Harvard Medical School will hereafter offer a new degree in medicine in addition to the time-honored M.D. It will grant the degree of Doctor of Medical Sciences (M.S.D.) to men who have specialized in their training in research work and the laboratory development of medicine rather than the clinical branches. It is hoped that by making a feature of this department more medical students will be attracted to research work. Dr. David L. Edsall, Dean of the Medical School, in announcing the new degree, states that in the laboratory branches there is really a disturbing paucity of capable and well trained instructors, and that if things go on as at present the laboratory branches will suffer seriously in both their instructional and investigative activities.

Harvey Society Lecture.—Sir Walter Fletcher, Secretary of the Medical Research Committee of Great Britain, will deliver the Tenth Harvey Society Lecture at the New York Academy of Medicine, Saturday evening, April 16. His subject will be: "The State's Relation to Medical Activities in Great Britain."

Argentina Plans to Honor Gorgas.—President Yrigoyen of Argentina is understood to have under consideration the participation of Argentina in the construction of a great scientific laboratory at

Panama, which is being planned as a memorial to the late General William C. Gorgas.

Delaware to Care for Mental Defectives.—As the result of a survey made by the United States Public Health Service in collaboration with the Children's Bureau, officials engaged in the care of mental defectives have become interested in the establishment of a bureau of mental hygiene in connection with the State Board of Charities. As a result of their efforts the Legislature has appropriated \$60,000 for improving the care and treatment of the mental patients in the State Hospital at Farnhurst. A training school for nurses specializing in neuropsychiatry will be opened, which will include occupational training and physiotherapy.

Protest Reduction of Medical Service.—A bill is now pending before the New York State Legislature, recommended by legislative committees charged with its preparation, which provides for a reduction in the appropriation to State institutions for the insane. The measure is being vigorously protested by the State Charities Aid Association and others interested in the efficiency of the State hospitals.

Medical Standards Endangered in Missouri.—Two bills affecting medical practice are before the Missouri State Legislature. The first deprives the State Board of Health of the power which it now has of deciding upon standards which medical schools must achieve before their graduates will be allowed to practice in the State. If this bill should become law a graduate of any school could receive a license provided he passed the State board examination. The second bill compels all hospitals that are exempt from taxation to permit any licensed practitioner of any school to treat a patient in the institution who desires his services. The medical societies of St. Louis and other cities have entered vigorous protest.

Medicine Popular With Exchange Students.—Out of a total of twenty-four exchange students of the Commission for Relief in Belgium Educational Foundation at work in America, ten are devoting their time to the study of medicine. Five come from the University of Brussels, two from Louvain, two from Liège, and one from Ghent. These students are studying in Johns Hopkins, California, Harvard, Columbia, University of Pennsylvania, Cornell, Yale, and Stanford. The Commission has also made some provision for the rehabilitation of Belgian Universities wrecked during the war.

Tuberculosis Decreases in England and Wales.—The figures given out by the Ministry of Health show that deaths from tuberculosis in England and Wales numbered 46,312 in 1919, as against 53,073 in 1917. Statistics for 1920, so far as they are available, indicate another decrease for last year.

Legislative Hearing on the Health Center Bill.—At the hearing on the Health Center bill before the Finance Committee of the Senate at Albany on March 30, the measure was opposed by representatives of the Professional Guild of Kings and Queens Counties, the Physicians' Protective Association of Erie County, the New York Medical Association, the Medical Society of the State of New York and the Medical Society of the County of New York. The bill was supported by State Commissioner of Health Dr. Hermann M. Biggs, a representative of

the State Charities Aid Association, and a member of the State Hospital Commission. No representative of the rural communities, for whose benefit this measure was ostensibly offered, appeared to advocate it, but an ex-member of the Assembly from Ontario County appeared in opposition to it as not demanded by conditions among those whom he formerly represented. Dr. Biggs presented a number of maps showing the devastated areas throughout the State which had been denuded of the practitioners formerly ministering to these sections and which the health centers were expected to repopulate if they were established. Some opposition was expressed to the methods employed by the health authorities to advertise their health campaigns. Another objection was that New York City, though benefiting in no way from this legislation, would be taxed for one-half of the whole amount expended for health centers throughout the State. It was the consensus of opinion at the end of the hearing that the bill would not be reported out of committee.

Physician Contests State Ruling.—Dr. Frank D. Jennings of Brooklyn recently applied to Supreme Court Justice Van Sicken for an injunction restraining Mr. Walter R. Herrick, State Commissioner of Narcotic Control, from enforcing a regulation promulgated last December requiring physicians to issue prescriptions for cocaine, morphine, and other habit-forming drugs on triplicate blanks issued by the Commissioner's office. Dr. Jennings contended that the regulation constituted a violation of his rights and those of other physicians.

Vaccination Rulings Differ.—Health Commissioner F. E. Harrington of Minneapolis has recently ruled that children may go to school whether vaccinated or not, and no children are vaccinated without the consent of their parents. He states, however, that in the event of an epidemic of small-pox he would be empowered to exclude from school any children who were not vaccinated. In New York vaccination is practically compulsory. Hugh McCullum More of Port Richmond, Staten Island, was recently convicted for a second time for failing to send his daughter to school, the reason being that he would not consent to have the child vaccinated. He was fined \$25 by the court and given the alternative of spending five days in jail. He has been given a few days to make up his mind which he will choose.

Prescriptions for Liquor Checked Up.—The Prohibition Office has checked up the prescriptions written for liquor in a little over a year, and finds that 13,800,000 prescriptions were written by 45,000 physicians who are licensed to prescribe liquor for patients. Most of the prescriptions called for one pint of liquor.

Physicians Reduce Fees.—Owing to the prevalence of unemployment and the reduction of wages, the physicians of Donora, Pa., have reduced their charges to the pre-war level.

The Camp Merritt Base Hospital Officers' Association will hold its second annual dinner on Saturday evening, April 9, 1921, at the New York Athletic Club, New York City. Dr. Carter S. Cole, 853 Seventh Ave., New York, is chairman of the dinner committee.

Children Given Ether to Cut Living Costs.—As the result of an investigation in Westfield, Mass., it

was learned that young children in that city were receiving sugar lumps soaked in ether to reduce their appetites. The children when questioned said the ether was given them to reduce their appetites and to quiet those who were noisy. The matter has been taken up by the State health and educational authorities.

Madame Curie will be received in the White House by President and Mrs. Harding on May 20, when she will be presented with the gram of radium in behalf of American women who have contributed funds for its purchase. Before Madame Curie goes to Washington she will be greeted by the University Women of America in Carnegie Hall, New York.

Dr. H. S. Brode has been re-elected president of the Walla-Walla County (Wash.) Tuberculosis League.

Dr. James D. Blevins of Beaumont has been appointed Director of the Bureau of Communicable Diseases and Assistant Health Officer of the Texas State Board of Health.

Dr. J. D. Osborn of Cleburne, Tex., has been appointed Surgeon General of the United Confederate Veterans, to succeed Dr. Derring J. Roberts of Nashville, who recently resigned.

Dr. Olin S. Pettengill of Salem, Mass., has been appointed Superintendent of the Essex County Tuberculosis Hospital.

Charitable Gifts and Bequests.—Of the \$1,000,000 set aside for charitable purposes by the will of Mrs. Annie Hurt of Washington, D. C., \$500,000 is devised for the erection and maintenance of a home in Washington for needy and destitute blind people. Approximately \$500,000 is to be equally distributed among the Children's Hospital, the Sibley Memorial Hospital, the Home for Incurables, the Washington City Orphan Asylum, and the House of Mercy.

Organizations of Professional Men Affiliate.—An attempt is being made by the Milwaukee County (Wis.) Medical Society to affiliate societies of physicians, dentists, and pharmacists in Milwaukee into an association which shall direct public policies as they affect these professions and have charge of legislative matters affecting these three professions. The organizations coming into the association would remain intact so far as their scientific activities are concerned.

Vacancies in the Medical Corps of the United States Navy.—Surgeon-General E. R. Stitt announces that there are at present a large number of vacancies in the Medical Corps of the Navy, and examinations are held at frequent intervals in several of the coast cities of the United States, and also at Chicago, Ill. For the present appointments will be made directly into the Medical Corps of the Navy instead of by preliminary enrollment in the Naval Reserve Force. As a consequence of this change successful candidates who may be ordered in attendance on a course of instruction at the Naval Medical School will be given an examination upon the completion of such course for the purpose of determining the value they have received from the instruction, but not with a view to determining their position in the regular service, this being accomplished by the entrance examination. Circulars of information for persons desiring to enter the Medical Corps of the Navy may be obtained by ad-

ressing the Surgeon General, U. S. Navy, Navy Department, Washington, D. C.

The Interstate Association of Anesthetists will hold a joint meeting with the Canadian Society of Anesthetists, and the Ontario Medical Society at the Clifton House, Niagara Falls, June 1-3, 1921.

The American Proctologic Society will hold its twenty-second annual meeting at Boston, Mass., June 3, 4, and 6, 1921. The headquarters of the Society will be at the Hotel Braemore. Dr. Ralph W. Jackson, 251 Cherry Street, Fall River, Mass., is secretary.

The American Association of Anesthetists will hold its ninth annual meeting at the Hotel Bellevue, Boston, June 6 and 7, 1921. Dr. F. H. McMechan, Avon Lake, Ohio, is secretary.

The American Medical Editors' Association will hold its fifty-second annual meeting at the Hotel Lenox, Boston, Mass., June 6 and 7. Dr. Joseph MacDonald, Jr., 15 East 26th Street, New York City, is the secretary.

The New York Electrotherapeutic Society was organized on March 9, 1921, and the following officers elected: *President*, Dr. Victor C. Pedersen; *Vice-Presidents*, Dr. Harold D. Corbusier and Dr. I. Seth Hirsch; *Treasurer*, Dr. Hermab C. Frauenthal; *Secretary*, Dr. Richard Kovacs. Regular monthly meetings will be held on the first Wednesdays of each month to which all physicians interested in electrotherapeutics are welcome.

The Italian Medical Society has been incorporated in Brooklyn, N. Y., and Dr. G. De Zoanna has been elected president. The purposes of the new society are to erect an Italian Hospital in Brooklyn, and to encourage friendly relations between Italian and American physicians.

Medical Society Elections.—THE FIFTH DISTRICT (S. C.) MEDICAL SOCIETY, including physicians of Chester, Fairfield, York, Lancaster, and Kershaw Counties, has recently reorganized and elected the following officers: *President*, Dr. W. R. Walker, Chester; *Vice-Presidents*, Dr. G. W. Poovey, Lancaster, and Dr. W. M. Love, Chester; *Secretary and Treasurer*, Dr. G. A. Hennies, Chester.

THE JACKSON COUNTY (ARK.) MEDICAL SOCIETY, at its annual meeting held in Newport, March 11, elected the following officers for the ensuing year: *President*, Dr. O. A. Jamison, Tuckerman; *Vice-President*, Dr. H. O. Walker, Newport; *Secretary and Treasurer*, Dr. Ira H. Irwin, Newport.

The International Red Cross Committee, at its meeting in Geneva, Switzerland, on March 30, elected the following officers: *President*, Gustave Ador, formerly president of Switzerland; *Vice-Presidents*, Sir Edward Stewart, Great Britain; Dr. Livingston Farrand, United States; Signor Ciralo, Italy; General Mille, Spain; M. Kuwato, Japan, and U. S. Guehoff, Bulgaria.

New Interstate Medical Organization Planned.—Doctors of Superior, Wis., and Duluth have named a committee to consider the formation of an Interstate Medical Association, to which doctors of northern Wisconsin and Minnesota, and the upper peninsula of Michigan would be invited to belong. It is proposed to hold meetings twice a year. On the committee are Dr. W. E. Ground and Dr. A. G. Hovde of Superior and Dr. C. L. Haney of Duluth.

Obituary Notes.—Dr. ROBERT B. ENGLISH of Baxter Springs, Kan., a graduate of the Missouri Medical College in 1874, died suddenly of heart disease on March 13, at the age of seventy-one years.

Dr. GEORGE WALTER HOCHREIN of Chicago died unexpectedly following an operation for gallstones at the Mercy Hospital, on March 21, at the age of forty-two years. He was a graduate of the Northwestern Medical School, in 1906, and a member of the American College of Surgeons. He had been a member of the staff of the Mercy Hospital for some years.

Dr. W. PRESTON BEAULIERK of Concord, N. H., a graduate of the University of Vermont Medical College, in 1896. He was a member of the American Medical Association and the New Hampshire Medical Club.

Dr. MILO A. JEWETT, United States Consul at Trondhjem, Norway, died on February 25. He was a graduate of Harvard Medical University Medical School, and was for a number of years physician to the State Insane Hospital at Danvers, Mass.

Dr. CHARLES E. SMITH of Gettysburg, Pa., a graduate of Hahnemann Medical College, Philadelphia, died after a protracted illness at his home, on March 16.

Dr. IRVIN WILLIS of Omega, Ga., a graduate of the Atlanta School of Medicine, in 1908, died suddenly, on March 16, at the age of forty-three years.

Dr. B. B. BUELL of Vermillion, Ohio, was run down and instantly killed by a passenger train, on March 15. He was a graduate of the Cleveland College of Physicians and Surgeons, in 1909, and was thirty-eight years of age.

Dr. GEORGE E. ELLIS of Denver, Colo., a graduate of the University of Buffalo Medical Department, in 1891, died about March 14, at the age of fifty-three years. He formerly practiced medicine in Sherman, N. Y.

Dr. ADOLPHE LERAY, chief of the x-ray laboratory of the St. Antoine Hospital, Paris, died at Enghien, on March 26. Dr. Leray was a victim of x-ray burns incurred in the course of what are believed to be successful efforts to find adequate protection from the x-rays. During the war Dr. Leray made 35,000 radiographs, for which he was decorated by the French Government with the Legion of Honor.

Dr. MAJOR H. WESTBROOK of Olmstead Falls, Ohio, a graduate of the Western Reserve University Medical Department in 1899, died suddenly while making a professional call in Brecksville on March 22, at the age of fifty-three years.

Dr. ROBERT W. SMITH of California, Pa., was almost instantly killed on March 21, when a passenger train struck the automobile in which he was riding. He was thirty-one years of age and a graduate of Jefferson Medical College.

Correspondence.

PANEL DOCTORS IN THE BRITISH ARMY.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—My attention has been drawn to the report in your issue of the 22nd January, 1921, of a meeting of the Philadelphia County Medical Society held on 27th October, 1920, and particularly to the remarks made by Dr. J. E. Sweet.

I am sure Dr. Sweet will be glad to know that he unintentionally misled his audience when he said that "he did not think any of the medical officers (of the British Army) were panel doctors." As Convener of the Scottish Medical Service (War) Emergency Committee I speak with authority and I can vouch for the absolute accuracy of the following figures:

General Practitioners in Scotland on the Insurance Panels on 4th August, 1914..	1766
Of these there served in the Army or Navy	610
General Practitioners in Scotland not on any Panel.....	402
Of these there served in Army or Navy..	124

The approximate total of medical men from Scotland of all classes—Consultants; Whole-time Officials and young graduates who joined the services immediately on graduating was 1560.

NORMAN WALKER, M. D., F. R. C. P.

7 MANOR PLACE,
EDINBURGH, SCOTLAND.

OUR LONDON LETTER

(From Our Own Correspondent.)

LONDON, March 16, 1921.

Thoracic Surgery During the War.—It has been stated on more than one occasion that the greatest advance made in surgery during the war was in thoracic surgery. In the development American surgeons played a prominent part and introduced new methods of technique. Of the British surgeons who dealt chiefly with this branch of surgery none had more experience or took greater advantage of this experience than Mr. George E. Gask. This authority gave a lecture on the subject (the second Lettsomian lecture) before the Medical Society of London on Feb. 21, 1921. He pointed out that, owing to the nature of the warfare, surgical and medical treatment had to be remodelled to meet the changed conditions. The wounds inflicted were of three classes: Those received (1) from rifle or machine gun; (2) from shrapnel balls; (3) from portions of shell and bomb or grenade. In moving actions the first of these predominated; in trench warfare fragments of shell were the chief cause. At casualty clearing stations the causes of death could be divided into two classes: (a) Those which occurred about thirty-six hours after injury; (b) those taking place later. Those in the first class were almost entirely due to the severity of the injury combined with the loss of blood. The prolonged invalidism following chest wounds was mostly due to infection of the pleural cavity and its sequelæ. Mr. Gask said it became clear that the principle to be aimed at was the early mechanical cleansing of the wound, both the chest wall and the injured viscera, before organisms had time to grow. This was attained by excision of the damaged and devitalized tissue and the removal of any foreign bodies, followed by early closure of the wound by delayed or primary suture. In the opinion of the lecturer this was the greatest contribution to military surgery which was made in the late war. There had been two bugbears which appeared overwhelming to surgeons attempting this. One

was a dread of opening the chest under a general anesthetic lest the resulting pneumothorax should cause respiratory failure. The second was their fear that the manipulation of a recently wounded lung might restart bleeding, which might prove beyond control. A wide opening should be made in the chest, so that the thoracic viscera would be brought into view. Patients with thoracic wounds were found to bear operation well, and they took the anesthetic well. Moreover, one pleural cavity could be opened widely without any grave danger. The fear of the danger from the mere handling of the lung was not justified. Thus, it only became necessary to decide which were the best cases on which to operate and to devise the best routes. A certain proportion would get well without operation; some required operation to save life or to obviate a long illness. In the intermediate cases there was room for difference of opinion. The teamwork done in the last war had made a great impression on the minds of those who participated in it. They were agreed that operation should be undertaken as soon as the initial shock of the injury had passed off and before sepsis could occur; usually it could be done about six hours after the patient reached the clearing station; i.e. twelve to twenty-four hours after receiving the injury. The speaker drew attention to the fact that it was not until July, 1917, that a memorandum was issued to medical officers emphasizing the value of treatment of open wounds of the thorax by immediate temporary closure by suture. An incision near the fifth rib enabled any part of the pleural cavity to be reached and dealt with. It had been found that manipulation of pleural contents could be carried out freely without causing any dangerous fall in blood pressure, and portions of lung tissue could be excised without fear. The lung, being a well-aerated vascular organ, was able to withstand infection. Gas gangrene of the lung itself was rare, whereas anaerobic infection of the pleural cavity was frequently met with. The surgeon should leave the pleural cavity dry and clean. The chest should always be closed in layers. Patients with hemothorax should be carefully watched for signs of infection, so that on the first occurrence of symptoms more active measures could be adopted.

The Treatment of Pulmonary Tuberculosis.—The lay press has so exploited the Spahlinger treatment of consumption that it has greatly aroused public attention. Despite the fact that Dr. Addison, the Minister of Health, explained clearly in Parliament the attitude of the Ministry toward the matter, and stated that, as it was a secret remedy, the difficulties in the way of proper investigation were practically insurmountable, many of the daily papers clamor for such an investigation. However, according to the *Evening Standard* of a recent date, there is a probability of an expert investigation into the claims made on behalf of the Spahlinger treatment for consumption being embarked upon. Moreover, the writer in this journal states that they had Herr Spahlinger's assurance that to an authoritative body he would disclose all the facts and processes of the treatment. It would be interesting to know if, when

he submitted notes of the treatment to the French Academy of Science, he disclosed all the secrets of the method. Dr. Addison declared that, on account of the secrecy maintained as to its constitution and method of preparation, it had hitherto been found impracticable for the recognized research laboratories of Great Britain to investigate its properties and effects. Does the discoverer now intend to reveal these secrets to an authoritative body? If not, the investigators must be considerably handicapped in their work. Again, to be certain that an individual is cured of pulmonary tuberculosis is a question of a very considerable period of time. But when all these points have been taken into consideration, it is satisfactory to learn, on the authority of the paper just quoted from, that certain specialists are considering holding an independent inquiry, so that the public may have a pronouncement on the treatment after it has been carefully investigated by those qualified to pass an expert judgment on the matter.

Encephalitis Lethargica.—According to promise, the Ministry of Health has issued recently a memorandum on encephalitis lethargica. Dealing with the history of the disease, it is pointed out that similar outbreaks have occurred in the past; for example, in 1865, the "strange fever" described by Willis, and epidemics characterized by nervous symptoms and lethargy in the seventeenth and eighteenth centuries. So far as is known the malady is caused by a virus which is filtrable, probably gaining entrance through the nasopharynx, and which sets up inflammatory changes in the nervous system. There does not seem to be any clear evidence that there is a relationship between encephalitis lethargica and epidemic hiccup, which has been observed in parts of this country during the past few weeks. The conclusions arrived at by the investigators who compiled the report for the Ministry of Health are that the disease "appears to belong to that group of maladies, including cerebrospinal fever and acute poliomyelitis, in which the pathological agent is much more frequently present in the human organism than the clinical symptoms indicate. An attack of the disease may be regarded as the result either of the breakdown of the immunity to the effects of the virus which the individual who harbored it had up to the time enjoyed or of a non-immune person having become freshly infected with a strain of the virus, which has attained a degree of pathogenicity that can be considered as specific." No specific treatment is available.

Obituary.—Sir Charles Cameron, M.D., passed away in Dublin on Feb. 27 last. He was in his ninety-first year. Of Scotch descent on his father's and of Irish on his mother's side, Cameron was born in Dublin. He studied medicine in Dublin and chemistry in Germany under Liebig, and at the early age of twenty-three was appointed professor of the Dublin Chemical Society. He did not take a medical qualification until thirty-eight years of age, when he obtained the license of the King and Queen's College of Physicians. He was appointed Professor of Chemistry in the School of the Royal College of Surgeons of Ireland in 1875.

A few years before this date, however, Cameron was made Medical Officer of Health for the city of Dublin, a post which he held up to two or three years from the time of his death. In 1835-6 he was President of the Irish Royal College of Surgeons; in 1886 he received a knighthood and in 1892 he was given the Harben gold medal. He was the recipient of honors almost too numerous to mention. Socially he was a delightful man and one of the most witty raconteurs of his day. His wit was of the sparkling kind and, in spite of his descent, had nothing of the proverbial Scottish "pawkiness." An example of his powers of repartee was shown some years ago when he was giving evidence before a Parliamentary committee, inquiring into a bill introduced by the Corporation of Dublin for the enlargement of the city boundary and the inclusion therein of certain suburban townships. It happened that Cameron himself lived in the suburbs and thus escaped the higher rates of the city. This fact was brought out during his cross-examination. The counsel, thinking to make a point against him, said: "You do nothing, then, to relieve the rates of the city." "Indeed I do," replied Cameron; "I relieve them of nineteen hundred a year." He was a voluminous writer on scientific subjects and also wrote a "History of the Royal College of Surgeons in Ireland," "Recollections," "An Autobiography" and a volume of poetry.

Lord Moulton, great lawyer and great chemist, died on March 9. Lord Moulton was one of the men who played a great part in winning the war. Although up to the time of the outbreak of the war a distinguished English judge, he was also known to scientific men as a great scientist and especially for his knowledge of chemistry; yet to "the man in the street" he was absolutely unknown. In an eloquent tribute to him by T. P. O'Connor in the *Daily Telegraph*, March 10, the writer says "that if his career had ended when he had attained almost the highest judicial honors, it might have been considered prosperous rather than brilliant; but the war brought him his opportunity, not of getting greater fame, for his work was unknown to the public at large, but of more valuable service to the defense of his country in her hour of need. He was attached to the Ministry of Munitions, and then there was seen, perhaps, one of the most extraordinary of all the phenomena of a war so rich in strange transformations, that a man who had spent his life over books, in law courts and in the peaceful debates of forums was engaged in contriving the deadliest weapons in the work of man-killing. Lord Moulton knew Germans, the German mind, the German language and German science, and, above all, German ruthlessness. The example they had given of employing the best scientific brains to add ruthlessness, horror and savagery to warfare, he bettered, for by constant research and experiment he was able to apply British science to the same purpose, to meet ruthlessness with ruthlessness, craft with craft and deadliness with deadliness. If the Germans brought in the hideous weapon of poison gas, it was the business of Lord Moulton and his associates to bring in a gas more poisonous and deadlier; if the Germans discov-

ered a new and deadlier explosive it was the business of Lord Moulton to invent a newer and still more deadly explosive."

 5. Recent Progress in Neurology. Isador H. Coriat.
4. Acute Empyema Complicated by Whooping Cough.—William Reid Morrison relates a case in point, in which rib resection and valve drainage of the chest under local and paravertebral anesthesia were employed. Ten months after the operation the patient, a little girl two years and five months old, presented symmetrical chest expansion, with no deformity. New rib had grown into the bony defect, and the chest was otherwise negative. In such complicated infections of the chest, novocaine is the anesthetic of choice, injected locally and paravertebrally. Ether, chloroform, or other general anesthetics are distinctly contraindicated. An indirect opening into the pleural cavity is infinitely preferable to a direct one, because in the latter case air rushes in and out of the chest continually, with each respiration. This causes partial lung collapse, which, in turn, favors cavity formation and chronic empyema, as the lung cannot fully expand. A valve fashioned from the soft tissues themselves is more efficient than any mechanical valve.

 6. The Effect of Phosphorus in Rickets. D. B. Phemister, E. M. Miller, and B. E. Bonar.
2. Industrial Lead Poisoning.—Marvin D. Shie bases this discussion on material drawn from experience gained during a study of lead poisoning in several industries, during which he made thorough physical examinations, including laboratory work, of more than 900 workers exposed to the lead hazard. Eighty of these were found to be suffering from lead poisoning in various degrees of severity, and ninety-five others had sufficient signs and symptoms of plumbism to warrant a tentative diagnosis. Certain signs and symptoms of plumbism have been given somewhat more importance as diagnostic points than they deserve. These are anemia, basophilic degeneration of the red cells, hypertonus, and constipation. Pronounced anemia is present in only relatively few cases; in many severe cases there is no anemia whatever. The pallor that is usually present is, therefore, due to some other cause, possibly a constriction of the peripheral blood vessels. Basophilic degeneration of the red cells is rare in chronic cases, and its value as a diagnostic point, even in acute cases, has probably been overrated. The presence of hypertonus is extremely variable. The cause of this variance is unknown; the difference in the form of the lead to which the different groups are exposed may have something to do with it. Hypertonus is nearly always present during attacks of colic. Although constipation is usual, it is not invariably present. The assumption, therefore, that a patient who is not constipated does not have lead poisoning is fallacious. Many cases of plumbism, especially acute cases, occur without constipation. A point of diagnostic value which appears to have escaped recognition, except by Hayhurst, is the presence of mononucleosis in chronic

cases. This is almost invariably present. The presence of a lead line is also extremely variable. In the treatment of plumbism prophylaxis is of much more importance than the curative treatment. By means of proper working conditions and medical supervision on the one hand, and the observance of the rules of personal hygiene and common sense on the other, together with cooperation between employers and employees, the incidence of plumbism in American industries could be greatly decreased. If the cause of the poisoning is removed the prognosis, except in a few cases, is good even without medical treatment. If, however, the lead continues to exert its deleterious effects through small, steady doses, the case steadily progresses, finally terminating in some form of paralysis or in some of the common degenerative diseases. As a rule, lead poisoning is a disabling rather than a fatal disease, although in chronic cases it undoubtedly hastens death.

3. The Diagnostic Significance of Jacksonian Epilepsy.—George Wilson gives brief histories of seven cases in point, and concludes that Jacksonian spasm is by no means diagnostic of a lesion of the motor cortex. Probably the commonest cause of this form of spasm is idiopathic epilepsy itself, and a careful examination with close scrutiny of the facts and history may prevent many errors in diagnosis. A person with Jacksonian epilepsy should not be operated on unless other signs and symptoms of intracranial disease are present.

4. Action of Mercurochrome-220 on the Gonococcus.—Swartz and Davis state, as the result of laboratory investigations, that mercurochrome-220 shows a powerful germicidal effect on the gonococcus; that the gonococcus is about forty times as susceptible to the action of the mercurochrome-220 as *E. coli*, and that solutions of mercurochrome-220 lose their germicidal potency on standing, and should therefore be used only when freshly made.

6. The Effect of Phosphorus in Rickets.—Phemister, Miller and Bonar, following up previous observations, detail briefly the histories of two patients showing the effects of phosphorus and cod liver oil on rickets, and two showing the influence of phosphorus alone. They found that the end-results produced by phosphorus, and the combination of phosphorus and cod liver oil, were quite similar. The method of action is little understood. In the case of cod liver oil the result might be attributed to the presence of fat soluble A, but this could not be the explanation for the action of phosphorus. There is a trace of phosphorus in cod liver oil in organic combination, but it is improbable that it is present in sufficient quantity to exert any influence. Clearly phosphorus, and also cod liver oil, in some way restore the power of normal ossification, which in rickets is temporarily lost. This refutes the contention of Wegner, who thought phosphorus incapable of assisting in ossification in rickets until some other factor restored the altered calcium metabolism to normal.

1. The Arris and Gale Lecture on the Cause and Prevention of Myopia.—F. W. Edridge-Green confines his discussion of this subject to acquired myopia, leaving out of consideration that due to congenital defect, in which the axis of the eye is longer than normal, and that due to increased refraction of the media. These causes are very rare in comparison with the acquired defect, in which, through elongation of the eyeball, the anteroposterior axis is increased and myopia induced, because the images of the external objects are formed in front of the retina, a concave lens being required to bring the images on the retina. The detailed examinations of some thousands of cases of myopia fail to convince the writer that a single case of myopia had been

either caused or increased by the use of the eyes for near work. It is very doubtful whether the use of the eyes for near work has anything to do with the production of myopia, and certainly nothing has been definitely proved. The causes of myopia are discussed under the heads of predisposing and exciting. The most common of the usually accepted predisposing causes is heredity. This may be a special weakness of the sclerotic to give way under the pressure or to become affected by certain diseases. Again, the anatomical arrangements for preventing the distortion of the eye may be defective. The first directly exciting causes of myopia are certain diseases, as measles, whooping cough, and bronchitis. Lifting and various exercises which increase intraocular tension may be exciting causes of myopia, the mechanism of the production of which is described. When it is considered that an increase of 1 mm. in the anteroposterior axis of the eye corresponds to three diopters of myopia, it will be seen that very little stretching is necessary in order to produce a perceptible amount of myopia. Numerous cases could be given of myopia and detachment of the retina through whooping cough. A young musician with low myopia, in indifferent health, was advised to take a rest and spend a year on a farm. He found that digging caused him great pain in the eyes, headache, and bleeding at the nose. His myopia rapidly increased, although he had no previous discomfort with his eyes in musical work. The recommendations which have been made by ophthalmic surgeons with reference to position in reading and writing, lighting, ventilation, and other hygienic conditions are advisable, but they do not seem to produce much effect in the prevention of myopia. In diseases which produce myopia, such as measles and whooping cough, special care should be taken of the eyes, particularly in those with a hereditary tendency to myopia. In measles the light should be arranged so that the child does not point its eyes downward, and the head should be raised as much as possible. During convalescence exercises should be carefully regulated; those forms which raise intraocular pressure, particularly when associated with back pressure, should be avoided. It is probable that the sclerotic, like other parts of the body, can be strengthened by suitable exercises. In the training of children in whom the eye is growing, when the coats of the eye are much softer than in the adult, those exercises which cause pressure and lead to myopia should be avoided. Any occupation which involves heavy lifting is not suitable for a myopic. It is particularly in those who have sedentary occupations, who are not in fit physical condition, and who have an hereditary tendency to myopia, that these forms of exercise should be avoided. Careful regulation of exercises, especially in the debilitated, is necessary. All exercises should be performed as far as possible in the erect position, with the eyes pointing forward. The ordinary games and sports, like cricket, tennis, running, and archery, are beneficial, and do not cause myopia. Standing erect and swinging light Indian clubs is a very useful form of exercise for people with sedentary occupations. Boxing is not suitable for them. In myopic children special exercises can be devised so that every muscle may be developed without causing an increase in the myopia.

4. The Bacteriological Investigation of a Case of Plague.—V. M. Synge and Joseph W. Bigger relate the occurrence of plague in a patient who resided within about a quarter of a mile of the docks, but who had no connection with shipping or sailors. The locality in which she resided has been free from plague both before and after her infection. The clinical findings and bacteriological investigations which definitely proved the disease to be bubonic plague are detailed. There can be no doubt, from these studies, that the organism was a true *B. pestis* and that the patient was suffering from bubonic plague. The method of infection is unknown. Both the municipal and port sanitary authorities failed to find any unusual mortality among rats. A number of rats were killed and sent to the writers for examination, but all were healthy. The fact that the patient owned a cat which alternately went on hunting expeditions and slept on her bed, may possibly be a link in the chain of infection. Nearly five months have elapsed since the occurrence of this case, and no further cases have been recorded.

3. A New Principle in the Surgical Treatment of "Congenital Cleft Palate," and Its Mechanical Counterpart.—H. D. Gillies discusses the principle involved, and W. Kelsey Fry details the prosthetic treatment advocated. The ideals aimed at are: Perfect speech, perfect mastication, normal nasal respiratory function, and, in so far as a displaced maxilla causes deformity, a normal bony contour. Gillies summarizes his part of the discussion thus: All unoperated hard palates have normal occlusion of the noninvolved teeth. Nearly all operated hard palates have abnormal occlusion of the noninvolved teeth. Nearly all operated palates have nasal intonation to speech and narrowed features and nasal passages. Most unoperated adult cases have enjoyed good health. Most palate cases require a dental plate, whether operated or not. He recommends: (1) Suture soft palate as far back as possible in the pharynx by detachment from hard, making the hard palate defect greater; (2) fill the hard palate defect by appliance from earliest infancy, even at the bottle or breast stage. For the lip he recommends early operation; for the palate, before speech development or later. Fry states the prosthetic advantages of this combined surgical and mechanical treatment as, first, the ease with which restorations of the hard palate can be performed by prosthetic means as compared with the difficulty with which the prosthodontist is confronted in the case of the soft palate; and, secondly, the absence of distortion of the dental arch, with resulting loss of masticatory function, which is unfortunately only too frequent in cases in which the hard palate has been restored by surgical means. The aims of dental treatment for these cases are considered under the following headings: (1) To aid feeding until such time as the surgical operation is thought advisable. (2) To construct an appliance to hold the epithelial inlay in position at the time of operation. (3) To construct an appliance to maintain the surgically restored soft palate in its correct position and, if necessary, to stretch it in a backward direction so as to enable it to make contact with the posterior wall of the pharynx. (4) To construct a permanent prosthetic appliance to restore the loss of the hard palate and, if necessary, the anterior portion of the soft palate.

4. The Treatment of Sprue by Massive Doses of Sodium Bicarbonate.—Aldo Castellani finds that the administration in sprue of massive doses of sodium bicarbonate by mouth and intravenously, in conjunction with the usual dietetic measures, gives satisfactory results in a large number of cases, especially as regards the intestinal symptoms of the malady.

2. A Preliminary Report on Pylitis in Pregnancy, with Report of Cases.—Greer Baughman bases this com-

munication on the histories of three cases of pylitis in pregnancy, selected because they were studied over a considerable period of time. All were treated with pelvic lavage, pyelograms being taken from time to time as the pelvic size changed, provided the condition of the patient warranted this added discomfort. All were private patients treated in a private hospital. The histories are summarized as follows: (1) In all the cases the right pelvis was principally involved. (2) In the first two cases the bladder was early and persistently involved. In the last case the bladder was occasionally inflamed. (3) In the first two cases the colon bacillus was the exciting cause. In the last case the staphylococcus albus. (4) In all of the cases the curve representing the sizes of the right and left pelvises is almost parallel. (5) The symptoms in all cases improved under irrigation. (6) The most marked improvement was noted following delivery in all of the cases, showing that the obstruction was due to the uterus and its contents. (7) The fact that the right kidney of the second case is congenitally small will account for the continued reduction of function upon that side. (8) There was noted a compensatory increase in function upon the side that was less involved. (9) It was possible to irrigate these cases within two weeks after delivery. (10) None of the cases had elevated temperature during the puerperium. (11) Even in enormous dilatations, as in Case III, where the pelvis held 100 c.c., a cure is possible. (12) Living babies were born in the cases in which labor was induced at the selected time, while the woman who entered labor before the time set for the induction of labor gave birth to a dead child.

7. Splenic Leucemia Associated with Pregnancy.—George W. Kosmak made a survey of the reported cases of leucemia complicating pregnancy in which a fairly definite diagnosis from the blood picture was made, finding ten cases. To this number he adds two well-developed and subsequently fatal cases, observed within a comparatively short interval of time. The ages in the twelve cases varied from twenty-four to forty, the majority being between thirty-two and thirty-six. With the exception of Peterson's case, all were multiparæ. A possible hereditary history is mentioned in only one case. The parity varied from three to nine. In most of the cases there is a history of living children that showed no tendency to the disease up to the time of the report, but, in a few instances, it is recorded that the babies died at varying periods from a few days to five months after labor. In four cases mention is made of the birth of macerated or stillborn fetuses. Among the twelve cases the mother survived in but two, but how long these mothers lived is not stated, neither is the subsequent course of the disease given. In the majority of cases it is found that the woman survived but a short time after labor. One of the writer's patients died before delivery took place, the second died in two weeks. In every instance but one (his own case) in which the definite diagnosis is presented, the splenomedullary type of the disease was observed. In many cases the authors mentioned a prodromal period in which progressive emaciation, anemia, and loss of strength were noted soon after pregnancy, from which no recovery resulted, and during which period the woman again became pregnant. The leucemia itself does not therefore appear to be a deterrent factor to conception. In any case where an anemic patient fails to recover under proper treatment a more minute and detailed examination of her blood should be made with reference to the possible diagnosis of leucemia. The occurrence of pregnancy in this disease indicates a most unfavorable outlook for the mother and conception, therefore, must not be allowed to take place where the condition is suspected. The prognosis is undoubtedly worse in the pregnant than in the nonpregnant state; and whether the association is accidental or not is immaterial. Where the disease is already present abortion seems to be indicated, with a rapidly progressing course and a fatal issue. The presence of an enlarged spleen is an almost constant factor in the disease, and should lead one to look for this sign in every anemic patient. The value of the x-ray in leucemia has been brought forward; but in the event of a pregnancy its application as a cure for the disease may work an undoubted harm on the fetus and the

induction of labor should be done before radiation is begun. It is important to distinguish between the acute and chronic forms of leucemia.

1. Differences of Opinion in the Treatment of Industrial Injuries. Carl Scheffel.
2. Trench Foot.—Etiology, Pathology, Bichloride Treatment. John F. Van Pelt.
3. True Gastric Pain. W. H. Foreman.
4. The Value of the "No Good"—Eurus continued. Douglas H. Stewart.
5. The Surgical Heart of the Child. Maxwell Quackenbos.

1. Differences of Opinion in the Treatment of Industrial Injuries.—Carl Scheffel reviews briefly some of the published opinions on the subject involved, from the variance in which he deduces that this branch of medicine is as yet very little systematized. Most industrial surgeons seem to agree that iodine is the best primary antiseptic to apply to wounds, but here the union of agreement commences and ends. It would be a great step forward if industrial surgeons could employ uniform and standardized methods to produce uniform results. Only in this manner can industrial surgery progress.

3. True Gastric Pain.—W. H. Foreman points out that true gastric pain is the result of adequate gastric tension. Ordinary gastric conditions or processes are not connected in consciousness, but are only concerned in reflex physiological gastric function. Pathological processes or conditions, either organic or functional, in the stomach or stomach wall, or outside of the stomach, such as fermentation, hypermotility, disturbance of gastric tone, inhibition of pyloric obstruction, peptic ulcer, cancer, reflexes from disease of any of the visceral or stomatic structures, functional or organic disturbances of the nervous or endocrine systems, or psychical influences, may induce gastric tension adequate to produce true gastric pain.

1. Some Clinical Observations in Mental Diseases. Max A. Bahr.
2. Origin and Significance of Tics. H. Laxson.
3. Large Strangulated Umbilical Hernia. Scott Edwards.

1. Some Clinical Observations in Mental Diseases.—Max A. Bahr considers not the cases presenting a well pronounced type of mental alienation, but the class of persons who present in their clinical aspect psychological defects which are usually considered harmless or of too trivial a nature to cause any special harm, much less medical or legal restraint. The known progressive tendency, however, of such lesions, together with their baneful influence and even at times vicious tendencies upon the higher cerebral functions, renders such mental unsoundness the very soil which constitutes the borderland of insanity, and from which grow and develop all forms and degrees of actual insanity. That the clinical field embraced by these dwellers on the borderland of insanity is a very large and varied one is certain, and the numerous clinical, pathological, sociological and medico-legal problems involved, are of the greatest importance. Analysis of these cases will serve to show how apparently slight defects or anomalies of mental constitution operating in certain temperaments will combine with a train of circumstances to bring an individual to total failure as a contributing member in our social life. Within the area of these borderland cases one must include the cases of psychasthenia with its impulsions, obsessions, doubts, phobias, mental anguish, agitation, as well as psychopathic exaltation and depression, constitutional inferiority, disorders of the stream of thought, disorders of volition, of the emotions, of the memory, of attention, and of the personality, whenever such disorders are more than transient. The various abnormal traits of character which are noted in the histories of such cases are defects of adaptation, defects in the capacity of the individual for acquiring knowledge; such characteristics as self-depreciation, conceit or self-pity; in exaggerated measure the tendency to shun society; such traits as selfishness, suspiciousness, jealousy, and such

traits as conscientiousness and scrupulousness, which in their normal development are useful qualities, but which in their exaggerated form work in a way to interfere with efficiency. Also moods and irritability are to be considered which determine the habitual or episodic reactions of elation or depression and likewise such abnormal traits as touchiness and sensitiveness. It is needless to state that most good can be done for these patients in the incipient stage. The early recognition of the various abnormal traits may enable one to prevent the development of an actual psychosis by early appropriate treatment. Prophylaxis through education of the public is important.

3. A Study of the Reactions Following the Transfusion of Blood.—Paul W. and Mildred C. Clough consider the reactions following transfusion the chief difficulty in the use of blood transfusion, and divide these into the following general groups: (1) Reactions following the use of compatible blood; (2) so-called hemolytic reactions, following the use of incompatible blood, where the cells of the donor are agglutinated or hemolyzed by the serum of the recipient; (3) severe reactions occurring in patients who have previously received many transfusions, following the injection of blood from a donor belonging to the same blood group as the recipient, and therefore compatible in the ordinary sense. The common form of reaction following transfusion is the febrile type. These reactions follow the injection of compatible blood and cannot be foreseen by preliminary blood tests. Outspoken reactions occur in 20 to 30 per cent. of the cases, and milder ones in 20 per cent. more. The severer reactions are disagreeable, but very rarely harmful, and they seem not to lessen the benefit the patient may derive from the blood injected. The cause of these reactions is still in dispute. Some can be avoided by painstaking care in technique. The most important factor is probably the change in the platelets associated with incipient coagulative changes in the blood. Injury to the red cells by the citrate is possibly also a factor. The hemolytic type of reaction follows the injection of incompatible blood—that is, blood from a donor whose cells are agglutinable in the serum of the patient or of other individuals belonging to the same group as the patient. These reactions can always be foreseen by adequate preliminary tests. These reactions begin early in the course of the transfusion, and have a characteristic symptomatology which should be familiar to everyone attempting a transfusion, and which will usually enable one to recognize them promptly, and to interrupt the transfusion before a fatal dose of incompatible blood has been given. Some of the severe reactions occurring in patients with pernicious anemia who have received a large number of transfusions apparently do not fall into either category. They may occur after transfusions from donors belonging to the same blood group as the patient, and may be associated with hemolysis and hemoglobinuria. It is important to test the action of the recipient's serum on the donor's cells, but it seems probable that the methods now in use will not suffice to foresee and avoid all such reactions. While it is not yet possible to eliminate all such reactions

following transfusion, nevertheless with adequate preliminary tests and careful technique the danger involved is so slight that it should never deter one from giving a transfusion when one is indicated.

4. On the Administration of Digitalis to Children with Diphtheria.—Hugh McCulloch makes the following observations: (1) Diphtheria toxin, either experimentally or clinically, produces anatomical and functional changes in the structures of the heart by direct action. Clinical manifestations of cardiac failure are due to these alterations of function and not to changes in the vagus center or nerve. (2) The effect of diphtheria toxin on the heart is similar in many ways to the effect on the heart of digitalis, either directly or through the vagus nerve. (3) The administration of digitalis to patients with diphtheria is contraindicated because there would result a summation of effects in the same heart. (4) With our limited means of estimating the optimum therapeutic amount of digitalis, or of controlling its effect on the various structures of the heart, this summation constitutes a real danger to the life of the patient. (5) Measures for providing rest for the heart other than the administration of digitalis should be adopted.

Ulcerogangrenous Vaginitis from Fatal Mercurial Intoxication.—Jaeger describes two cases of this very rare sequence and gives the subject monographic treatment. It has occurred almost wholly in syphilitics under treatment with the metal. Both patients were of this type and both had received intramuscular injections, the one of grey oil and the other of salicylate of mercury. Both patients were also receiving neosalvarsan and appeared to be reacting well to the treatment, which was interrupted in the first patient to allow her to menstruate. After the period had expired two ulcers were noted on the vulva. It was at this juncture that grave general symptoms appeared which caused the woman to seek ward treatment in the hospital. The vulva was much swollen and a gangrenous ulcerative process was evident. There was not the least evidence of salivation or mercurial sore mouth and no lesions are mentioned save the local ones. The process apparently extended upwards until it caused perforation of the vagina and peritonitis. Autopsy, however, showed the presence of acute nephritis and a condition of the colon and rectum suggesting that of the vagina. The intense inflammation, diphtheroid false membranes, ulceration, and mass necrosis caused an extensive bacteriologic research, revealing nothing definite; but metallic mercury could be isolated from the mucosa of the vagina. The second case was quite similar to the first, although in this patient mercurial necrotic stomatitis was present while there was no colitis. The case also ended fatally and autopsy caused some slight doubt that the vaginal ulceration was purely mercurial; no mention of finding mercury in the mucosa suggests that the test here was negative and the metal may have acted only indirectly through systemic poisoning.

Anaphylaxis.—Laumonier refers to a recent article on this subject by Kopaczewski, who makes a distinction between the hemoclastic crisis which follows a first injection and that which follows a second injection of the same substance. The second is the only one to produce the anaphylactic shock so-called. The hemoclastic crisis has been renamed the colloidoclastic. The phenomena produced by the second injection have been explained by sensibilization and the interval has been regarded as a period of incubation not seen after first injections. During incubation the soil is provided for the result of the second injection which follows suddenly. The preparation has to do with the laws of physical chemistry. The author gives the original views of Richet, Besredka and others, from which we must conclude that the antigen or often essentially harmless first injection is a complex nitrogenous

molecule. But a harmless atoxic serum may be rendered toxic by simple methods, such as centrifugalization or contact with kaolin, starch or gelose; who shall say then that anaphylaxis cannot be due to some change effected in the antigen itself? Theories involving a chemical explanation have been succeeded by another in which physics is concerned, and which is bound up in the colloidal condition of living matter. This takes us back to the subject of first injections in which the colloidal hypothesis is entirely plausible. Hence if the two sets of phenomena are reduced to a common motivation involving the colloidal equilibrium, the interval of latency is the subject which chiefly requires explanation. The phenomenon of colloidoclasia may be regarded as humoral, while the anaphylactic shock with its period of latency is essentially cellular, in Kopaczewski's opinion.

Brazil-Medico.

January 15, 1921, xxxv, 3.

Cataphrenias.—Austregesilo refers to a new syndrome which has been seen in syphilis (pseudoparesis) and after epidemic encephalitis. Other cases are seen in false dementia precox occurring in succession to some of the infectious diseases. Cured dementia precox is doubtless an example of this cataphrenic syndrome. The latter seems to find its justification at least in Brazilian psychiatry, for several of the leading authorities have moved to adopt the term. Naturally the movement is not unopposed, and the author admits that time alone can decide the question. At present the latter, as stated above, is restricted to a few affections, as precocious pseudoparesis, curable dementia precox and certain cases of the latter type which have followed epidemic encephalitis of the lethargic type. The author does not desire to extend this conception of disease beyond these limits. Kraepelin himself, as all know, has modified his original conception of dementia precox and it may be susceptible of further change. As far as can be inferred, Ulysses Vianna first applied the term cataphrenia to early syphilitic paresis, which proved to have been wrongly diagnosed. The same syndrome was then seen by French authors to follow lethargic encephalitis, and the fact is also recalled that certain apparent precocious dementers who traced their disease to an antecedent infectious disease have recovered—these also having presented the same syndrome. The author curiously omits a summary of the latter.

Finska Läkaresällskapet Handlingar.

November-December, 1920, lxii, 11-12.

Osteomalacia.—Schaumann describes the first case of this disease in Finland. The patient was a woman aged thirty-three. There was a marked family history of locomotor troubles, pains in the limbs, rickets, enuresis nocturna, convulsions, etc., but apparently no other case of osteomalacia. The subject herself, who was well grown, healthy, and mentally normal at the age of fourteen, developed the same pains in the legs and inability to walk as had been present in several near relatives and took to her bed for several months. But the trouble was an intermittent one, with notable remissions and tending to be worse in the spring. The patient did not menstruate until the age of eighteen, and five years elapsed before the periods were regular and normal. Six years after the onset there were noted several skeletal changes, such as approximation of the hips to the thorax. Five years more expired before the long bones began to bend without fracture. The condition became progressive and she became permanently bedfast. On examination she was found absolutely free from rickets. The osteomalacic pelvis was well shown, and there was kyphoscoliosis. The x-ray showed chiefly atrophy of the skeleton. Gross changes in the endocrine glands could not be shown and the only symptom pointing in this direction was brown pigmentation on the right side of the face and neck. The hair and genitals were normal save for a possible enlargement of the left ovary. The author believes that rickets and osteomalacia are closely related. The severer forms of rickets are also very rare in Finland.

Book Reviews.

THE ANATOMY OF THE HUMAN SKELETON. By J. ERNEST FRAZER, F.R.C.S., Eng., Professor of Anatomy in the University of London, and Lecturer in the Medical School of St. Mary's Hospital; Examiner in Anatomy for the University of London; Examiner in Anatomy for the Primary Fellowship of the Royal College of Surgeons of England; Formerly Examiner in Anatomy for the Conjoint Board of the Royal College of Physicians and Surgeons. Second Edition. With 219 Illustrations. Philadelphia: P. Blakiston's Son & Co., 1920.

In this handsome volume the author presents the study of the human skeleton from a novel, and practical, point of view. He considers the bones in their relation to the other structures of the body, rather than as isolated objects. The result is a volume which is stimulating and useful, and which demonstrates the real medical and surgical value of a knowledge of the bones when studied as here demonstrated. The book is profusely illustrated with pictures which are both artistic and of practical utility. The medical man who is some years away from his anatomical studies would do well to procure this book and go through it carefully; he would find much to instruct and much to interest him. The author is to be congratulated on having produced a volume as interesting as Holden's "Osteology," to which, indeed, it would serve as a valuable sequel.

INJURIES TO THE HEAD AND NECK. By H. LAWSON WHALE, M.D. Camb., F.R.C.S. Eng.; Capt. R.A.M.C. (T.F.), Formerly Capt. I.M.S. (Retired); The Queen's Hospital, Sidcup; No. 83 General Hospital; and Surgical Specialist to No. 53 General Hospital, B.E.F.; Surgeon for the Ear, Throat, and Nose to the London Temperance Hospital; and to the Hempstead General Hospital. With a Preface by Colonel FREDRICK F. BURGHARD, C.B., M.D., F.R.C.S. Octavo of 322 pages with 130 Illustrations. New York: Paul B. Hoeber.

From the preface by F. F. Burghard we learn that the author of this book was brought in contact with head and neck injuries from the earliest days of the war to its close: first at Boulogne, then at the Queen's Hospital at Sidcup, at which latter place he was able to follow up end results in a way which was not possible in the English hospitals in France. The author, therefore, had unusual opportunities for the study of these conditions and one does not have to read very far before he is impressed with the author's intimate knowledge of his subject. Also, it is soon seen that a large part of the text is based upon actual cases treated by the author or cases which came under his immediate observation. The injuries referred to were principally bullet or shrapnel wounds; but much of the text covers conditions that might easily occur from industrial accidents or in civil practice, as, for example, in the chapters on hemorrhage, injuries of the jaw, localization and extraction of foreign bodies, rhinoplasty, plastic surgery of the face, etc. One of the important features in the discussion of injuries of the face is the suggestion of what should be done at once and what should be left until a later date; and throughout the book we find treatment advised in accordance with a common sense view of conditions as they may be found under varied circumstances rather than in accordance with hard and fast rules. For those who have to deal with traumatic conditions this book should be a great help.

SURGICAL PATHOLOGY AND MORBID ANATOMY. By SIR ANTHONY A. BOWLEY, K.C.B., K.C.M.G., K.C.V.O., F.R.C.S. Surgeon in Ordinary to His Majesty the King and Consulting Surgeon to St. Bartholomew's Hospital; President, Royal College of Surgeons of England. And SIR FREDERICK W. ANDREWS, M.D., F.R.S. Lecturer on Pathology at St. Bartholomew's Hospital; Professor of Pathology in the University of London. Seventh Edition. With 210 Illustrations. Philadelphia: P. Blakiston's Son & Co., 1920.

This book has long been recognized as a serviceable introduction to the study of pathology. It is not by any means a complete textbook, but it occupies a useful place as a guide to the surgical student. The present edition contains new material on Gas Gangrene, Shock,

and Tetanus, and the size of the printed page is larger than before. The illustrations, which have always been a feature of the book, have been redrawn on a larger scale. The book will continue to hold its place as a singularly clear exposition of the main principles of surgical pathology.

NOUVEAU TRAITE DE MEDECINE. Publié sous la direction de G.-H. ROGER, F. WIDAL, et P.-J. TEISSIER. Fascicule Premier. Maladies Infectieuses. Paris: Masson et Cie., 1920.

This book forms the first volume of a projected series of twenty-one volumes of what we should call a system of medicine. From the prospectus presented and the list of the contributors announced it promises to be an excellent one in every respect. Certainly the authors who have been secured include nearly all of the French physicians of note.

The first five volumes are to be devoted to the infectious diseases. The one at present before us is devoted chiefly to the bacteriemias with some special applications. It is generally very well presented, but it would seem that the subject of infections caused by the influenza bacillus deserves more attention than Macaigne gives it. Certainly it is a very insufficient presentation of an infection that was so general and so carefully studied as this was. Hudelo's chapter on gonococcus infections is excellent, but we regret to find so little consideration given to the question of vaginitis in children and the importance of the careful study of vaginal smears from infants and small children. On the whole the book is excellent, and if the whole series is as well done it will be a valuable work of reference so long as it is not out of date. There is something to be said for the loose-leaf idea.

THE AMERICAN RED CROSS IN THE GREAT WAR. By HENRY P. DAVISON, Chairman of the War Council of the American Red Cross. New York: The Macmillan Company, 1920.

In the 292 pages which constitute the text of this interesting volume one may obtain a fairly comprehensive idea of the scope, character, and effect of the work of this great organization at home and overseas during the World War. The enormity of the task and the manner of its execution are concretely told in figures in the appendix, and the text, full of interesting incident, holds the attention from beginning to end. Many of "the millions of women, children, and men who, through the American Red Cross, worked and sacrificed that the misery of war might be alleviated," to whom the book is dedicated, will find in it an interesting account of the monumental undertaking which they so successfully consummated.

A TEXT-BOOK OF PHARMACOLOGY AND MEDICAL TREATMENT FOR NURSES. By J. M. FORTESCUE-BRICKDALE, M.A., M.D. (Oxon), M.R.C.P. London, Physician to the Bristol Royal Infirmary and Clinical Lecturer in the University of Bristol. London: Hodder and Stoughton; New York: The Oxford University Press, American Branch, 1920.

This is one of the Oxford Medical Publications and carries on the high traditions of the series. The letter press and the illustrations are excellent, and leave nothing to be desired. The purpose is to give an explanation of the principles underlying medical treatment in the expectation that instructions will be more thoroughly carried out, the more the nurse in charge understands. Excellent as the book is, it is open to question whether it will be useful to nurses; with the limited amount of time at the disposal of nurses, there is too much; to convert nurses into a local house physician, there is too little. But all the explanations of chemical and physical theories are simple and straightforward, and the pharmacology is clear and good. Perhaps there is too much emphasis placed on the synthetic drugs, some of which are rarely used. Especial mention may be made of the section on Sera and Vaccines.

In the second section of the book one would expect to find more emphasis on those parts of treatment which are usually entrusted to nurses, but the author has not done this and if anything there is too much attention given to details regarding which there is divergence of opinion among physicians. The appendices are most useful.

Society Reports.

AMERICAN ASSOCIATION FOR THORACIC SURGERY.

Third Annual Meeting, Held in New Orleans, La., May 1, 1920.

Dr. RUDOLPH MATAS OF NEW ORLEANS IN THE CHAIR.

I. President's Address: The Fundamental Principles of Thoracic Surgery.—Dr. WILLY MEYER of New York delivered this address. (See page 593.)

II. Thoracic Cavity.—1. Studies on the Effect of Trauma in the Thoracic Cavity.—Drs. F. C. MANN and C. A. HEDBLUM of Rochester, Minn., presented this paper. An investigation was undertaken to determine the cause of death or the development of a serious condition following intrathoracic operation. All experiments were performed upon dogs, kept under ether anesthesia of a constant tension. It would seem that one of the most potent causes of difficulty in intrathoracic operation lies in insufficient pulmonary ventilation. The compression of the lung, as could be produced by packing off the pleural cavity, was sufficient to prevent that lung from functioning until it was again insufflated. A serious condition could often be produced under very light ether anesthesia by different forms of intrathoracic trauma. This condition appeared to follow or was at least associated with reflex inhibition of the heart and respiration. No evidence was obtained that excitatory stimuli produced any permanent effect upon blood pressure or respiration, or in any way reacted adversely upon the condition of the animal.

Dr. HEDBLUM said that this study was undertaken in the hope that it might throw some light on the cause of the sudden death following thoracentesis. They had several such cases at the Mayo Clinic during the last few years. One was a man of sixty who presented signs and symptoms suggesting a purulent effusion some ten days following laparotomy. He collapsed immediately following a single negative aspiration, through an ordinary aspirating needle without any local anesthesia. Artificial respiration and stimulation failed to revive him. He was dead probably within five minutes of the aspiration. Unfortunately, a necropsy was not permitted. A second case was a girl of twelve years who gave a history of failing health, but without any definitely characterizing symptoms. X-ray showed a shadow in the lower portion of the left thorax. To rule out an effusion an exploratory aspiration was done under cocaine anesthesia. Immediately following withdrawal of the needle, after a negative aspiration, the child went into a clonic convulsion lasting perhaps nearly a minute. After a series of such attacks she died, about ten minutes after the onset. Necropsy showed tuberculosis of the central portion of the lower left lobe of the lung and a cerebral embolus. A third case was that of a young man of twenty-five, in excellent health, and having gained some twenty pounds following recovery from an influenza bronchopneumonia, complicated by a large empyema. The empyema had been reduced to 10 or 15 c.c. capacity under antiseptic solution treatment. One day, while the cavity was being irrigated with the hypochlorite solution, the patient remarked that everything was turning black before him. He lost consciousness and died in a few minutes. The brain in that case did not show an embolus. In all of these cases prolonged artificial respiration was instituted without avail. In support of the assumption that some of these cases might be due to some form of reflex inhibition, might be cited one case collapsing suddenly and dying following incision of the ear-drum. In addition to these fatal cases might be mentioned several who had recovered. One boy of sixteen developed a hemiplegia following aspiration of the lung for abscess, of which he still had a slight residue after ten months. Another developed a temporary blindness following the same operation. A child of ten also developed a temporary blindness following a drainage operation for empyema. Eye examination by Dr. Benedict failed to reveal the cause of the blindness. Another case was that of a residual sinus following resection of the chest wall for sarcoma,

done by Dr. Robinson three and a half years ago. The patient wanted the sinus closed. Bismuth paste injection was followed by temporary unconsciousness. On partly recovering consciousness he became so violent that forcible restraint became necessary. Complete recovery followed in twenty-four hours. Several other cases had developed slight symptoms following bismuth paste injection. These cases were presented without any attempt being made to account for these symptoms, other than to state that some of them were due to emboli, while others seemed to be due to a reflex inhibition. There might be other causes of which we were as yet unaware.

Dr. F. W. PARHAM of New Orleans, La., called attention bearing on this subject to three consecutive cases which showed, to his mind, that the positive pressure apparatus was not always absolutely necessary. The first case of resection of the chest wall which he undertook was in 1898, when he operated on a woman with an extensive disease of the chest wall without any differential pressure apparatus. When he opened the chest wall, which he did extensively, there was, of course, the usual development of a terrible pneumothorax. As it was his first experience, he was at a loss what to do, but suddenly remembered the suggestion of Payr; he pulled up and grasped the lung through an opening of five or six inches in diameter, brought it to the chest wall and sutured it, and the trouble subsided. The woman died a year later from a pneumonia. The second case was an extensive resection of the chest wall, which had already been reported by him and published in the "International System of Surgery" (Gould & Warren) with illustrations. Dr. Matas had at that time introduced before the State Medical Society the subject of improvements in thoracic surgery, and in that article he had suggested the method of Fell-O'Dwyer of positive pressure which he and Dr. John Smyth had been working on for some time. Dr. J. D. Bloom had added a bellows apparatus worked with the foot. When this case came into the hospital the speaker put this method into effect. The O'Dwyer cannula was introduced into the larynx and the bellows worked with the foot lever. The positive pressure was thus beautifully maintained. That trial convinced him that the chest ought not to be opened so widely without some differential pressure of the positive variety. He said that this resection involved the third, fourth, and fifth ribs for five or six inches. When a third case appeared, involving the lower right side of the chest with the diaphragm, he had one of their best laryngologists to assist him; he put the O'Dwyer tube into the larynx, but they could not keep it there, as the most violent reflex was started. He had to finish the operation without the assistance of the differential pressure. He resected the tenth, eleventh, and twelfth ribs for five or six inches of each with a portion of the diaphragm and, when the chest was opened, an aggravated pneumothorax developed. He caught the lung, as in the first case, and when he pulled it up it flattened out like a sheet of paper, then he tacked it to the diaphragm and chest wall and succeeded in finishing the operation without further untoward results. In this case he had nothing but the skin to cover the opening, everything else had been removed, and, therefore, he had subsequently to devise an apparatus to hold that side of the chest up. He believed this patient was still alive. In that case in which he had to operate without the assistance of the differential pressure, upon which Dr. Meyer had laid so much stress, he became convinced that the differential pressure was not absolutely essential, but when he compared the mental anxiety he suffered with the absence of this differential pressure, he could not see why one should not attempt to improve the apparatus for differential pressure. He believed Dr. Meyer was correct in the effort he was making to improve the methods of differential pressure to such a degree that they could more certainly be brought to their assistance in such cases. There was nothing more alarming to the operator or more disquieting than the pneumothorax which suddenly developed in proportion to the size of the opening.

Dr. JOHN L. YATES of Milwaukee, Wis., said he had the very good fortune to serve as a ward dresser at a hospital in Belgium and to study the effects at the time of operation, immediately after operation, and dur-

ing recovery of patients operated on after the so-called Duval method. Two things became obvious in watching this work. The first was the amount of traction required to expose the lung for operation when positive pressure was not used. The other point was determined in studying the fate of the acute pneumothorax, and there was a surprisingly large proportion which did not recover with advertised rapidity. He observed one case of complete pneumothorax, with closed chest and collapsed lung, a month after operation. In spite of treatment for ninety days thereafter, it was impossible to detect any improvement in his complete unilateral pneumothorax. When they started work as a team with the American forces, their experience in Belgium, together with experiments done on dogs, had led them to the conviction of the great importance of some form of differential pressure. Dr. Gwathmey worked out a simple, safe method of positive pressure, morphine-gas-oxygen analgesia. The apparatus was not cumbersome and utilized gas tank pressure. This brought up the question of collapse advanced by Dr. Mann. The duration of collapse varied, most of the wounded coming to operation more than twenty-four hours after injury. They soon came to the realization that if the collapse were due to collapsed bronchi, with absorption of air distal to the bronchial compression, reinflation was impossible because, if enough pressure was used (this applied to men as well as to dogs) to reinflate the lung under such conditions, sufficient strain was placed on the heart to produce acute and rapidly fatal dilatation. If the compression was due not to bronchial collapse, but merely to air cell collapse, the refilling of these air cells followed rapidly, and under, as Dr. Mann indicated as effective in the dog, 15 to 16 mm. positive pressure. Repeated inflation and deflation of the lung required by operations upon wounded men caused no demonstrable variation in systemic blood pressure. Traction upon a deflated lung sufficient to permit of a degree of exposure suitable for operation caused a fall of 40 mm. Hg. in systolic blood pressure in a few minutes. This observation was made upon a patient who had been found to show no variation when the positive pressures were changed. Facts of this type upheld the accuracy of the observation previously made in Belgium. Another point about differential pressure: In the repair of a lung injury, traumatic or surgical, one must recognize that any pulmonary tissue permanently out of function was a menace to the individual, either an immediate menace as a focus for the development of empyema or a subsequent menace through atrophy and consequent impairment of elasticity. If a considerable portion of a lobe was of diminished capacity, the entire lobe would shrink and thus cause a shrinkage of the whole side of the chest. The patient would be a better man if all permanently disabled portions of the lung were resected. How far must that resection be carried back? With the aid of positive pressure, inspection quickly determined the presence of essential functions, the pulmonary and bronchial circulations and the air circulation. All must be present to maintain respiratory function, and the limit of necessary resection was easily decided by cutting back the lung under constant inflation until red blood spurted under high pressure, blue blood spurted under low pressure, and pulmonary tissue was everywhere inflated. It was then possible to establish hemostasis and aerostasis so that function could be immediately reestablished by reapproximating the cut surfaces and by sewing the visceral pleura airtight. With differential pressure it was then possible to cause pulmonary inflation so the chest might be closed with minimal residual pneumothorax. They had observed the progress of the wounded in Belgium where this procedure was not followed, and could compare it with that of our wounded, and found that the method resulted, first, in the immediate comfort of the patient after operation, and then in the rapidity and completeness of convalescence. In larger hospitals for the non-transportables the lung ward was peopled with patients treated by other surgical teams as well as their own, and the comparison showed the closing of the chest with the nearest possible obliteration of the acute pneumothorax led to the greatest number of recoveries and the greatest rapidity of convalescence. As was well known, the great number of those who did not survive

and did not succumb immediately died later of empyema. Dr. Finney took the point of view that every man should have "a run for his white alley," and always encouraged them to operate on anyone who was still breathing and to disregard statistics. In this way some apparently certain fatalities were avoided. Later, in the Aigonne fighting, a method of airtight, one-way drainage was devised that could be instituted at the time of operation, and he felt that, had this point been settled earlier—that is, primary drainage as a routine—the awful mortality rate from empyema which occurred in those whose transportation was delayed might have been largely avoided. When the wounded were received early, this method gave an immediate mortality rate of 4 per cent. in 52 consecutive unselected patients. As to the rapidity of recovery, one must please remember that military surgery was not a question of life and death alone; it was also a problem of getting the living men back into the line with the least possible delay. They had one Irishman with three hates: sobriety, peace, and the Boche. He was operated upon under the above means and this man was back on duty six weeks after a resection of part of his right lower lobe and a repair of his diaphragm. He cited this instance simply to show the rapidity with which recovery could be accomplished with positive pressure during operation, with accurate repair of the parietal and visceral pleuras, and the institution of primary drainage.

Dr. GEORGE J. HEUER of Baltimore, Md., said that there were apparently many ways of achieving good results in thoracic surgery. Dr. Yates had just told them what he considered important principles in the treatment of thoracic injuries. Their own experiences were in many ways less satisfactory than his, for they were not a special surgical team appointed to do thoracic surgery. They had no special anesthetist, and had no intrathoracic pressure anesthesia apparatus. Under the circumstances they used ether by the drop method in operations upon the thorax. In 160 cases of penetrating chest wounds there were 45 with open sucking chest wounds in which immediate operation was performed without a pressure apparatus. In not a single case was there disturbed respiration during the course of operation. There was no death upon the operating table, no death afterward which could be ascribed to their method of giving anesthesia. They came to feel, therefore, that thoracic surgery could be done without fear of respiratory upsets without the use of the pressure apparatus. They agreed with Dr. Yates that any involved lung tissue should be resected, and this method was constantly followed. In regard to the question whether it was easier to operate upon the lung when expanded or collapsed, they had no method of comparison, for all their procedures were done with the lung collapsed. From his experience in operating upon animals he could say that resection of the lung might be more easily done with a collapsed lung than with an expanded lung. As to the treatment of the postoperative pneumothorax: In large wounds of the lung, where large resections were necessary, they had the feeling that the pulmonary wound would heal more rapidly with the lung collapsed, and, therefore, did not remove the air from the pleural cavity at the end of the operation. Their x-ray studies showed that the pneumothorax disappeared spontaneously within ten days. In regard to primary drainage of the pleural cavity at the completion of the operation, they invariably closed the thorax without drainage. In their experience there was a much larger percentage of postoperative infectious complications when the pleural cavity was drained than when the thorax was completely closed. As to their results: Their mortality in the seriously wounded, in whom resection of the lung was often necessary, was 25 per cent. As he read the literature, this mortality, although not the very best, was a very presentable one.

Dr. NATHAN W. GREEN of New York said he was interested to see that Dr. Mann had worked out the experiments on the dogs, and that Dr. Hedblom had been ably supported by him in carrying out the clinical work. In 1906-8 the speaker did considerable work on dogs in regard to the open pneumothorax and he found that the results, as he remembered them, were somewhat similar to those shown by Dr. Mann. Among

other things he did at that time, he dealt with trauma of the chest directly, not trauma of distant organs, and showed that in the opening of the chest they had a distinct lowering of the temperature after keeping it open for a long time, say an hour. Also, they found that the chest, when it was simply opened and nothing done (just left open under artificial respiration, which they did under positive pressure), would show an infection and was occasionally the seat of suppurative pleurisy from simple exposure to the air. He was glad to see that Dr. Mann had thrown his weight in favor of artificial respiration. It seemed the only rational thing to do to use all mechanical means at our disposal in order to insure the operative safety of these cases. Everybody knew one could do a lot of thoracic surgery without artificial respiration, but when one was doing cases, not acute cases, like those reported by Drs. Heuer and Yates, but, for instance, chronic lung abscesses, and, having no adhesions, wanted to bring the lung out to the chest wall so as not to get an infection of the pleural cavity, one knew that with artificial respiration he could get more comfort and peace of mind and a better operative result. In most cases of sudden death during anesthesia from ether he believed the breathing stopped first, the heart continuing for a short time, and, therefore, it seemed if one had the artificial respiration apparatus present he could in some instances ward off the sudden death which might otherwise be not only very disconcerting to the individual surgeon, but disastrous to progress in the whole field of thoracic surgery. The speaker said one should develop a vision for the future of thoracic surgery and do nothing to discourage the attempts now being made along these lines. Dr. Heuer had mentioned infection of cases after primary drainage. If the president, Dr. Meyer, were present he would come out strongly on the subject of primary potential drainage. If the pleural space were obliterated by positive pressure and the drainage were so placed that it could be made actual drainage, but was not actual drainage at the time of closing, it would not induce infection and would be a very efficient safety valve in case the accumulation of fluid should become septic. This procedure was especially desirable in all cases where one had to deal with a suppurative process in the lung. These cases are depleted in vitality, while the cases mentioned by Drs. Yates and Heuer were taken up after exposure but were mowed down in the pink of condition. No doubt their resistance to infection was greater than in those individuals who had been sick for some time. He thought Dr. Mann and Dr. Hedblom were to be congratulated upon their paper.

III. Heart.—1. Routes of Access to the Heart. Lessons Gathered from the Experiences of the World War.—Dr. RUDOLPH MATAS of New Orleans, La., read this paper, illustrated with lantern slides. (See page 595.)

Dr. YATES said in his experience with nearly two hundred chest injuries he never saw one involving the heart directly. Upon one occasion a patient's heart stopped beating just as he was to be operated upon for the relief of a perforated chest wound. It was decided to attempt cardiac massage and the ordinary type of fifth rib section, as advocated by Duval, was done. With very little traction the heart was brought to the chest wall, but massage through the pericardium was ineffective. The pericardium was therefore opened, adrenalin injected into the heart cavity and then direct massage was effective. The myocardium had been cut when the pericardium was opened, so that both heart and pericardium had to be sutured. This was accomplished easily. One was always impressed by one's personal limited experiences. In the normal individual, with the more or less elastic mediastinum, it was easy, with the lateral thoracotomy, to displace the heart where one could reach it. One could see from Dr. Matas' beautiful picture that if one wished to approach the posterior aspect of the heart, after the elaborate method of exposure, one must rotate it upward so that rotation was not avoided thereby. Fortunately, roentgenologic diagnosis made it possible to know which lateral approach was necessary, and the lateral incision made this of very little trouble. He would ask his hearers please to notice that Duval, the great champion of open thoracotomy without positive pressure in his exposure of the heart, preached against the establishing of an acute pneumothorax.

Dr. PARHAM said Dr. Matas had certainly gone over this subject thoroughly, and he seemed to be convinced of the great difference between these conditions as seen in the war and those seen in private practice. It seemed to him that they ought to encourage those efforts to devise some method of doing this work in the chest cavity and on the heart, especially with less mental anxiety to the surgeon. He would like to say one thing in regard to reducing the postoperative pneumothorax. It seemed to him that the suggestion, made some years ago by Witzel, that where it was desirable to reduce the pneumothorax it might be satisfactorily accomplished by putting in a catheter as the wound was being closed and introducing water into the pleural cavity; this was allowed to run out as the lung gradually expanded.

IV. Pleura.—1. The Treatment of Chronic Empyema.—Dr. CARL A. HEDBLUM of Rochester, Minn., presented this paper. The author made a comprehensive historical review of empyema, discussed the general principles of treatment, and presented a study of 150 cases of chronic empyema treated at the Mayo Clinic during a little more than two years. An extensive bibliography of 193 references was appended to the article, which was profusely illustrated. The minimum duration of the empyema in the patients treated was three months, the maximum duration twenty-three years. The process had been present for more than six months in 112 instances and more than one year in 65. Operation had been done elsewhere in 117 patients, many of whom had received operative treatment several times. Fifteen lesions were definitely proved to be tuberculous. Thirteen patients gave a history of primary pleurisy with effusion; all of these had had open drainage treatment elsewhere. Four methods of treatment were employed, as follows: (1) Simple rib resection, forty-two cases; (2) Dakin's solution, with or without minor drainage operations, fifty-one cases; (3) pulmonary decortication, thirty cases, and (4) plastic operation on the chest wall, twenty-seven cases. The first group, for the most part, included patients who had had faulty drainage, although in some bronchial fistulas were found, and in several there were foreign bodies in the cavities. Simple rib resection brought complete recovery in twenty-six cases, a persistent sinus at the last report in four, and death in one. Eight patients could not be traced. Of the tuberculous patients, one was greatly improved, one somewhat improved, and one was not benefited. The technique employed in the second group of patients, who were treated with Dakin's solution, with or without a minor drainage operation for a small residual cavity, consisted in irrigation through a catheter inserted into the old sinus, or through a stab wound by means of a trocar and cannula. The results were complete recovery, thirty-four cases; sinus at last report, six; no late report, six; convalescence not completed, four, and not benefited, one (tuberculous). In the patients who had a decortication, the operation was done under ether anesthesia through a rib-spreading exposure. Fifteen patients were completely cured without further surgery, and five after a secondary plastic operation for a small cavity. Three had a persistent sinus at the last report, one died following the operation, three died from other causes some time later, and three were still under treatment. The results of the plastic operations were a complete cure in fifteen cases, a residual sinus at the last report in three, and death in two. Four patients had not completed their convalescence, and three could not be traced. Five patients were definitely proved to be tuberculous. Small bronchial fistulas were present in a considerable number of patients successfully treated with hypochlorite solution. Large bronchial fistulas, 0.7 cm. or more in diameter, were present in ten. Four closed spontaneously, following wide-open drainage of the cavity, one was closed by cauterization, one by suture, and four by a skin plastic operation. In two cases of tuberculosis the fistulas remained open. In one instance of multiple fistulas in a case of bronchiectasis a closure of only a part of the fistula was secured. In four fatal cases one death was caused by sepsis and inanition following a rib resection for drainage, one by cerebral abscess following a plastic operation, one by tuberculous meningitis, also following a plastic operation, and one by influenza pneumonia following a decortication. Dr. Hedblom closed the ar-

ticle with the following tentative conclusions: (1) Chronic empyema had been recognized and treated during twenty-six centuries, but it was only sixty years since the first rib resection for drainage was done. The successive stages in the progress or treatment since that time were as follows: (a) Increasingly radical treatment designed to obliterate the cavity by the collapse of the chest wall, involving successively more extensive operations, and culminating finally in a complete radical resection. (b) A conservative trend manifested primarily in the modifications of the complete resection, but more in the attempt to preserve the chest wall and to restore the lung to its structural and functional relationships, as first advocated by Delorme. (c) The adaptation of the Carrel-Dakin hypochlorite solution technique to the treatment of chronic empyema cavities. (2) Chronic empyema was a disease which was not incompatible with life nor with a fair degree of health and usefulness. The principles of treatment should, therefore, be, first, the preservation of life, and, second, as far as possible the conservation of function. Shortening convalescence, while very desirable, should always be a subsidiary consideration. (3) The choice of treatment must be made with cognizance of the variable etiology and pathology of the process and the general condition of the patient. (4) A major procedure was indicated only if non-operative or less extensive surgical treatment reasonably might be considered less effective. (5) In case of sinuses and small cavities, adequate drainage was usually sufficient to effect a cure, with or without short preliminary hypochlorite solution treatment. It was at least open to question whether a radical operation was indicated in these cases for the sole purpose of shortening convalescence at the risk of an appreciably increased mortality. (6) Dakin's hypochlorite solution treatment was the method of choice in the treatment of the ordinary type of empyema cavity of any size for the following reasons: (a) The general condition of the patient was, as a rule, improved to a remarkable degree. (b) The cavity might be obliterated or greatly reduced in capacity by the liberation and expansion of the lung (resulting from the treatment). (c) If the lung expanded in part, the extent of a later operation would be proportionately reduced. (d) If the lung entirely failed to expand, the cavity would have become relatively sterile in preparation for operation, thereby lowering postoperative morbidity and mortality. (e) Pulmonary decortication would be materially facilitated in some cases, owing to the softening action of the solution on the visceral pleura. (7) A pulmonary decortication through a rib-spreading exposure after preliminary hypochlorite solution irrigation was the most conservative treatment for cavities that were not obliterated by drainage or Dakin's solution treatment alone. If such an operation was successful the lung was restored to its normal structural and functional relationship, thereby obliterating the cavity. If the operation was only partly successful, the magnitude of a secondary destructive operation was proportionately decreased. (8) Since it was impossible to judge with certainty before operation of the relative expansibility of the lung in every recent non-tuberculous case, a decortication should be done rather than a destructive operation, thereby giving the patient the benefit of the doubt. (9) If the lung did not expand, or if a considerable cavity persisted following decortication, a plastic operation was indicated. (10) If the cavity was of considerable extent or the patient debilitated, a two- or three-stage plastic operation was recommended. (11) The recognition of tuberculous empyema was often difficult. A history of a primary pleurisy with effusion seemed more often to signify a tuberculous condition than did a pulmonary lesion, unless the latter was active and extensive. A tuberculous empyema might be present in the absence of clinical or x-ray evidence of pulmonary involvement. The typical microscopic picture in the sectioned pleura or the demonstration of the bacilli in the exudate might constitute the only evidence in such cases. (12) A tuberculous empyema not secondarily infected should not be drained and should not be aspirated only for a considerable accumulation of fluid. For a tuberculous empyema secondarily infected, either by operation or spontaneously, drainage was necessary. (13) In the absence of bronchial fistulas and of bleeding, secondarily

infected tuberculous empyema might be markedly benefited by antiseptic solution treatment. The amount of fibrosis or other pathological change in the lung in such cases determined the degree of expansion of the lung, whether following antiseptic solution treatment or decortication. (14) If the lung failed to expand in whole or in large part, a several-stage operation designed to collapse the chest wall was indicated. Tuberculous patients were relatively poor operative risks. (15) Adequate drainage was the first indication in cases of empyema cavities which were draining through large bronchial fistulas. The fistulas might be obliterated spontaneously following such treatment. (16) Operative closure of bronchial fistulas that was necessary to complete healing. It might be accomplished by decortication of the involved portion of the lung with cautery, suture, or skin plastic to cover the opening of the fistula. Occasionally healing resulted from simple granulation of surrounding tissue after destruction of the epithelial lining of the bronchial stoma. (17) Closing the bronchus that was draining pus from within the lung might result in a secondary lung abscess. (18) A large bronchial fistula was a contraindication to Dakin's solution treatment. (19) Sinuses of variable duration were common following more or less complete obliteration of empyema cavities; a large proportion eventually were obliterated without radical treatment; for those which persisted, plastic operation was indicated. (20) Operative mortality in chronic empyema had been due largely to shock and infection. Reduction of the extent of operation and preliminary sterilization would materially lower this mortality.

Dr. F. W. PARHAM of New Orleans, La., presented a patient from the country whom he wished to throw, as a case, into the discussion. This patient, who had given him a great deal of trouble, had chronic empyema with a bronchial fistula, and he had so far feared to do anything more than improve his general condition. This young man had a pneumonia six years ago and was operated on subsequently for what was supposed to be empyema: resection of the rib was done, but no pus was found. Subsequently he was again operated on with the relief of a large amount of pus. In 1917 he came to the speaker; in September of that year he operated on him in the attempt to get a good exposure of the lung. He could hear the air rushing in and out, and hoped to find the opening which was delivering air into the cavity, but his condition became so bad on the table that he did not accomplish anything, and had to discontinue the operation. A few months later he attempted an extensive posterior resection of the chest wall and got a very good exposure, but he failed to find the bronchial opening. His general condition had very much improved; a tube was left in his wound all the time, for when it was removed the wound closed and his temperature went up, requiring a reintroduction of the tube. He could not carry out the Carrel-Dakin irrigations because of the irritation to the lung. He also tried dichloramine-T, but failed to accomplish anything. The fluid would immediately enter the bronchus and set up violent respiratory embarrassment. The object in presenting him today was to get some suggestion as to the best manner of closing the fistula. At one operation he got a very good exposure and attempted decortication of the lung, when he found bleeding was so free that he could not carry out even Ransohoff's suggestion of the lattice-work incision. This was the first time the speaker had seen him in a year. He weighed 136 pounds and was able to carry on an active life on a plantation. The suction was not so evident as when he last saw him. This was a type to which he believed Dr. Hedblom had not called attention, a large bronchial opening being the apparent cause of the non-closure.

Dr. CARL EGGERS of New York said Dr. Hedblom had covered the subject of chronic empyema very well, and he had ably called attention to the important points. When confronted with chronic empyema one might divide the subject into two groups, thus: patients who had had empyema and had a superficial sinus, and patients with a real cavity. The superficial openings that persisted might be due to several causes which were usually quite simple. One cause was epithelialization of the tract. Simple excision of the tract with the surrounding skin and muscle followed by suture would

lead to a cure. Another cause was osteomyelitis at the site of a formerly resected rib. In such cases one resected the rib a little beyond the primary resection, removing all granulation and scar tissue, and closure then led to a prompt cure. A third cause was infected granulations. These might occur in cases in which one had done a primary resection of a rib or in which a tube was introduced through an intercostal incision. Bony bridges might form in either case, irregular in character, and they allowed infected granulations to hide behind them, where they were inaccessible to treatment. Resection of these areas would lead to a cure. For the persistent deep sinuses or cavities there were various causes which might be divided into avoidable and unavoidable. The unavoidable ones they did not have to criticize, but if they had a large series of chronic empyemata in which the cause was avoidable they could try to prevent repetitions. By far the most common cause of chronicity was inadequate drainage. One must, therefore, maintain drainage sufficiently long and adequate until all infected material had drained out. Another common cause was an improperly placed drainage opening, either too far forward, allowing a channel to form between the diaphragm and the chest wall, or too low an incision. Usually in empyema the costophrenic sinus became obliterated early, and the resection of the eighth or ninth rib would give the best drainage. Another cause of chronicity was pneumothorax. That was a vague term as ordinarily employed and some men called any persistent cavity a pneumothorax. Dr. Eggers had a different conception of the condition. He thought there was a difference between chronic pneumothorax and a chronic empyema cavity. The latter was a residue of the pus collection in the chest which had compressed the lung, which for one of the reasons quoted was unable to expand completely, leaving a chronic cavity. When they spoke of a pneumothorax the condition was different; it was always the result of a primary collapse of the lung, due to two causes, either a too early operation, or the perforation of a pulmonary abscess giving a pyopneumothorax and allowing collapse of the lung. Other causes of chronicity were bronchial fistula, tuberculosis, and foreign bodies. If one, therefore, was confronted with a chronic empyema, one thought of these various possibilities and tried to find the cause most likely to be responsible in that particular case and then tried to eliminate it. In many cases it was possible to do this. Adequate drainage, instead of inadequate drainage, followed by antiseptic treatment, would cure a great many patients. After one had healed by conservative means all amenable to this form of treatment, there were still a number of cases which did not heal, just what percentage he did not know at that time. Dr. Hedblom had 27 out of 150. The speaker had seen many hundreds of chronic empyemata, and they had operated on 125 to 150 by the radical method. In a certain number a radical operation was a necessity. He believed about 2 or 3 per cent. of empyema cases required radical treatment of some form. Recurrence of empyema occurred more often when the cavity was not chemically sterilized, but it also occurred after careful chemical sterilization. He had looked for the cause, since he thought it was interesting why, under such conditions, there should be a recurrence. There were two causes, one was a lighting up of infection in a narrow recess in connection with an old cavity. These recesses existed most commonly along the diaphragm or in the costophrenic sinus, either anteriorly or posteriorly. The second cause of recurrence, and he believed an important one, was the fact that the pleural layer of chronic cases was an infected membrane. In chronic empyema the thick pleural layer, which was a dense scar, was, on the average, half an inch thick, and he had in a great many cases had sections made of this membrane, and in many instances it showed military abscesses scattered through the wall. In some cases these abscesses contained streptococci. These organisms might multiply and a little abscess could break through and develop a recurrence that, in a way, sneaks in favor of radical operations, because by such operations one removed all infected membrane.

Dr. LEON T. LEWALD of New York said the roentgenologist also had his part to play in the diagnosis of empyema. The distinction between the type of case

which had been reported by Dr. Eggers and the keeping up of the condition by a tuberculosis of a rib or a tuberculosis of the pleura could sometimes be determined by x-ray examination. He would like Dr. Hedblom to reiterate the cases of tuberculosis pleuritis that were in his series. He did not think one ought to be discouraged by the presumptive evidence of a tuberculous complication in the absence of positive proof of the tuberculosis of the pleura. He had 5,000 post-mortem examinations at Bellevue Hospital, and at that time his examinations all proved tuberculous pleuritis were very much less common than the text-books led one to believe. At the present time, in general hospital work, he was frequently asked to confirm what was suspected of being a tuberculous pleura, and there was no evidence from the x-ray standpoint of tuberculosis of the lung on either that or the opposite side, and even guinea pig inoculations failed to substantiate the suspicion. Dr. Walton Martin had reported a case in which they knew they had a tuberculosis of the pleura, and in which he had done an extensive resection, taking out thickened pleura which was distinctly tuberculous and so proven on microscopical section, and had in this case obtained a complete cure. In regard to the foreign bodies, incidentally, he would like to suggest that if red rubber was used for the drainage tube, it gave a more definite shadow under the x-ray than did black rubber. He had an instance of this in a case of Dr. Mathews', in which Carrel-Dakin solution was being used with a number of tubes, and they could not identify the position of one of the tubes. He suggested that it was possibly made of black rubber, which proved to be the case. Occasionally a tube which was not very dense might not be made out radiographically in an extensive exudate in the pleural cavity, particularly if made of black rubber.

Dr. OSCAR M. SHERE of Denver, Colo., made the following remarks by invitation. They had a good opportunity in Colorado to study tuberculous empyema, probably a little more than in some of the other States, and he was, indeed, pleased to hear Dr. Hedblom express his opinion against operation in the purely tuberculous cases where mixed infection was present. His own experience during the past 16 or 17 years in the J. C. R. S. Sanatorium of Denver bore out in a most forcible manner the truth of this statement. In former years they used to see about 2 or 3 per cent. of empyema in their cases; at the present time this percentage was much higher, owing to the fact that a good number of their empyemas were the sequence of artificial pneumothorax, so commonly employed nowadays in the treatment of pulmonary tuberculosis. A few months ago their senior resident collected some twenty-odd cases of tuberculous empyema and published a paper, which appeared in the December issue of the *American Review of Tuberculosis*, which might be read with interest by anyone who cared to peruse it. While one hesitated to lay down any hard or fast rules in the treatment of these cases, yet he believed in a certain classification which served him well when the question arose as to the advisability of operative interference. Thus he divided tuberculous empyema in three distinct classes: (1) The very acute cases, in which the onset was sudden, such as following a rupture of some part of the infected lung. These cases must not be operated on when the diagnosis was first established. Delay usually offered a better prognosis for the patient. (2) The subacute cases, wherein the exudate gave rise to dyspnea, fever, and increased cough—simple withdrawal of the pus under the most aseptic technique from time to time was the best method of treatment. (3) The chronic cases, wherein the above treatment had failed and the patient continued to be dyspneic, running a degree or two of temperature above normal and accompanied by anorexia and gradually progressive asthenia—these they operated on by rib resection and tube drainage with antiseptic irrigation until the cavity was sterile. When the latter was accomplished they endeavored to close the cavity by means of Beck's paste or skin flap transplantation. A small number of these patients required a thoracoplasty for the complete collapse of the entire lung before a cure was finally established. All their operative work was done under spinal anesthesia, since their medical staff was opposed to the use of general anesthesia in these patients. Dr. Shere

hoped to present some experimental data along these lines at some future meeting of this Association, accentuating some of the points which he tried to present at this meeting.

Dr. HEDBLUM, in closing, stated that, with a few exceptions, these were cases of chronic empyema cavities. A number of the cases had bronchial fistulae. In one case of ten years' duration there was a bronchial fistula near the vertebral aspect of the left lower lobe. It was closed by granulations, following cauterization and open drainage. There were several other cases closed by suture of the edges or by skin flap. Several closed spontaneously, following simple drainage. A number of patients treated by Dakin's solution irrigation at times tasted the solution, indicating the presence of small fistulae. Tuberculous empyema secondarily infected they had found difficult to deal with. Diagnosis of the condition was uncertain unless the tubercle bacilli were demonstrated. Conservative treatment often was of no material benefit, while radical treatment resulted in a relatively high mortality.

(To be continued.)

THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, Held February 9, 1921.

THE PRESIDENT, DR. MORRIS PIERSOL, IN THE CHAIR.

The Serum Treatment of Pneumonia: Serotherapy in Pneumonia; Its Clinical Aspects.—Dr. TRUMAN G. SCHNABEL read this paper, in which he said that the use of antipneumococcus serum dated back to the Klemperer Brothers in 1891, although it had been five years before this date that Fraenkel had noted the possibility of producing in animals a protective immunity against lethal doses of a pneumococcus culture. In 1896 Weissbecker reported favorably on the use of convalescent serum in lobar pneumonia. It was Neufeld and Händel who first reported work which made it quite evident that pneumococci were capable of being grouped into several different types from the immunological point of view. In 1910, with the opening of the Rockefeller Institute, Dochez and others took one of Neufeld's cultures and began what has been one of the most noteworthy pieces of research accomplished in this country. As a result of their efforts it now seemed quite certain, after about a decade, that serum of a horse immunized against the original Neufeld pneumococcus was of some value in the treatment of a pneumonia due to the same type organism. This pneumonia was Type I lobar pneumonia, and this diplococcus was now known as Type I pneumococcus. This serum, when properly used in appropriate cases, quickly freed the blood stream of the infective organisms and arrested the spread of the pulmonary lesion. It furthermore ameliorated the subjective and objective symptoms and had almost certainly lowered the mortality rate for this class of cases. After the intravenous use of this serum, as might occur after the parenteral injection of any foreign protein, there might follow one or more of three reactions: anaphylactic shock, the thermal reaction, and the serum disease. The first reaction occurred infrequently and was preventable; the second reaction could probably be prevented by paying attention to the proper injection technique, while the third reaction occurred in from seven to fourteen days after the serum injection and occurred in a varying percentage of cases. The rational treatment of acute lobar pneumonia should now include early sputum, typing together with the determination of the patient's protein sensitiveness. If the infective organism was the Type I pneumococcus, the Type I serum should be used in sufficient dosage at the earliest opportunity and at eight hour intervals until the critical phenomena occurred. If the facilities for typing were not available, or if the infective organism was not Type I, then there seemed to be no sufficiently controlled scientific or clinical evidence that any other univalent or polyvalent serum should be used. The Pennsylvania State Laboratories were prepared to type sputa for physicians in any part of Pennsylvania. It had not been possible to create in animal sera satisfactory cura-

tive antibodies against pneumococcus lobar pneumonia consequent upon Type II, Type III, or Type IV infections. There were in the literature some exceedingly favorable reports on the use of other sera than the Type I variety, and careful observers had felt that often the results after their use had been most striking. If a serum did no good therapeutically we were not certain that the so called parenteral protein reactions were without harm. The use of other sera in lobar pneumonia as well as in bronchopneumonia and the post-influenza pneumonias had been favorably reported upon in the literature, and those who had employed them were often impressed by the good results obtained. Plain horse serum, the chicken serum of Kyes, and convalescent, or post-critical, serum all had their enthusiastic supporters and excellent mortality rates. The pneumonias were, however, well known for their unrivaled variability. Their picture changed with the seasons, with the age incidence, and with the infective type of organism. Their clinical course, duration and mortality were dependent upon a multitude of factors. To control a laboratory experiment properly was oftentimes a difficult problem, but to control properly a clinical experiment was many, many times more difficult. As the difficulty of experimental control increased, so must the caution with which interpretations were placed upon clinical results increase.

Notes on the Bacteriology and Serum Treatment of Pneumonia.—Dr. H. L. BROCKMANN read this paper, in which he said that it had been a common observation during the influenza pandemic that streptococcal pneumonia gained unusual prevalence, while pneumonia caused by recognized "type pneumococci" had been relatively less common than had formerly been the case. Among the influenzal pneumonia cases, streptococci (including pneumococci) had been found in larger number than any other organism. Later in the pandemic hemolytic streptococci had become relatively more numerous. Fifty-six cases occurring at the University Hospital between October 2, 1919, and March 30, 1920, had been tabulated; 24 were diagnosed as bronchopneumonia and 32 as lobar. Blood cultures were taken in 44 of the cases and of these 7 were positive. Six proved to be pneumococci which corresponded in types to those found in the sputum. Hemolytic streptococcus was found in one blood culture. The mortality rate among those giving positive blood cultures was practically the same as those in which the cultures were negative. Judging by this series of 56 cases, the impression to be obtained was that during the period of 1919-20 there continued to be prevalent to an unusual degree pneumonias caused by organisms other than the well recognized fixed types. It was recognized that in given cases of well developed Type I lobar pneumonia, serum for type I pneumonia had a distinct value, the mortality under good conditions having been reduced by its use from 30 per cent. or higher to 10.5 per cent. For pneumonia caused by the other recognized types of pneumococcus, as well as by heterogenous Type IV and by other organisms, it was not practical to prepare and give effective sera. There were instances, however, in which serum withdrawn from patients just convalescent from pneumonia of these types might be given with very apparent advantage to patients in the midst of attacks of the same type. Dr. Stengel in the February number of the *Medical Clinics of North America* cited instances of this kind drawn from his experience with a series of lobar pneumonia cases prior to our entrance into the war and with a 1918-1919 series of influenzal pneumonias. He considered the facts that after a pneumonia crisis the cardiac action was so rapidly restored, the pulse rate diminished, and normal respirations resumed without discoverable change in the degree of consolidation or in the other physical signs, as indicating that the embarrassment of these functions was toxic in origin rather than mechanical. We had not yet reached a definite knowledge regarding the formation of antibodies in lobar pneumonia; but we did recognize at least a transient immunity following recovery. This was probably at its height just after the crisis. It was for this reason that the serum was obtained as soon after the crisis as possible. The treatment had probably not been employed to a sufficient extent, especially with due care

being given to typing of the pneumonia cases, to be able to forecast the real extent of its value. Experience thus far fully justified its employment wherever practicable. The general plan at the University Hospital for handling cases of pneumonia was as follows: On admission .5 c.c. of horse serum was injected into the skin. If the patient was sensitive, reaction would probably appear before typing had been done and other preparations made for giving sera, in event the case was one in which this form of treatment was indicated. This preliminary injection of horse serum also helped to desensitize the patient. Assuming that it was a type in which serum treatment was indicated, and the patient showed no sensitization, 75 to 100 c.c. of appropriate serum were given intravenously, by gravity, allowing it to enter the vein slowly over a period of fifteen minutes to one-half hour. This dose was repeated every six or eight hours until favorable results were established, the average total dose being about 250 c.c. If the patient was sensitive, as shown by the skin test, small, frequently repeated doses should be given first, or 15 c.c. given slowly, about fifteen minutes for 11 c.c., and the patient observed for reaction. If no reaction (tachycardia, restlessness, suffusion of eyes, dyspnea, or urticaria) occurred the remainder of the serum might be given more rapidly. Great care should be taken with known asthmatics.

Dr. HERBERT FOX said that there seemed no question about the value of Type I serum. As to the advisability of using convalescent serum from other types for other forms of pneumonia it was open to question as to whether we were at present in a position to say that this was a generally applicable procedure. It had been established in several ways that it might be undertaken under properly controlled conditions. All those who had used post critical convalescent influenzal serum in influenzal pneumonia had small doubt that the chances of recovery of those influenzal pneumonias was increased by the use of the serum. That the same was true of lobar pneumonia of Types II, III, and IV he was not able to say quite so definitely, but surely we saw after the introduction of the use of convalescent influenzal serum a very different outlook of the individual's recovery than before it was used. The serum of Type I horse or preserved serum of immune cases, should be warmed before being introduced into the body, and by all means should be diluted.

Dr. EDWARD H. GOODMAN said that the dominating type of pneumonia in the Presbyterian Hospital had been Type IV. In Type I there was no question that the mortality was decreased, the patient was made better, the blood stream quickly became sterile and all symptoms improved. The thing that seemed to him of importance was laboratory cooperation to determine the proper type. There was no reason why a type should not be returned within twelve hours in a hospital. He thought it was wrong in any case to use polyvalent serum.

Dr. JOHN A. MURPHY of Swarthmore said that he believed very properly controlled and treated cases in Type II, and particularly in Type III, showed some benefit, and that had been found in cases where the dose had been considerably higher than the ordinary 50 to 75 or 100 c.c. dose.

Dr. FRANK M. HUNTOON said that we could produce antibodies from Type I, both in human beings and in horses. There was no evidence up to this time to justify us in using Type II serum, but how could evidence be obtained if we did not try it on cases? That such types could be influenced by antibodies had been shown by experimental work they had been doing. They were not using serum, but antibodies derived from serums.

Morphine Allergy.—This phenomenon is well known in the ordinary subject, and even in the concentration of 1-1,000,000 the needle puncture will cause a wheal. It is necessary for a first sensitizing injection to be made. The maximum intensity is seen about six hours after the first injection. The phenomenon is not confined, as some believe, to morphine, but is seen with atropine and other alkaloids. In atropine, however, the period of maximum intensity is one hour after injection.—*La Presse Médicale*.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

OHIO STATE BOARD OF MEDICAL EXAMINERS.

Columbus, December 1-3, 1920.

ANATOMY.

1. Describe the structure of the prostate gland and give its anatomical relations.
2. Describe the gross anatomy of the larynx.
3. Describe the diaphragm, its principal openings and nerve supply.
4. Give the deep and superficial origin, course, and distribution of the tenth cranial nerve.
5. What arteries, muscles, and nerves would be severed in a cross-section at the middle of the humerus?

PHYSIOLOGY.

1. Define leucocytosis.
2. What postmortem tests should be applied to prove that air has entered the lung of a supposedly stillborn child?
3. Describe the different glands of the stomach.
4. What is the function of each class of foods in the nutritive process?
5. Give the origin and uses of lymph.
6. What is metabolism?
7. Give the function of the epiglottis.
8. Define reflex action and give examples.
9. Of the functions of vision, what is understood by accommodation?
10. What are the sources of animal heat?

CHEMISTRY.

1. Define physiological chemistry.
2. Define a carbohydrate and a hydrocarbon, giving an example of each.
3. What are pepsines, and how are they produced?
4. What is the reaction of normal gastric juice, and to what is it due?
5. What is hemoglobin? Name some of its properties and its functions.

MATERIA MEDICA.

1. Name the official preparations of bismuth, giving doses of each and methods of administration.
2. In cases of hyperpyrexia, name the three antipyretics you consider most efficient and safest. Give mode of administering each.
3. Name two drugs used as (a) cardiac sedatives, (b) cardiac stimulants, (c) cardiac tonics. Give dose of each.
4. Define (a) serum; (b) vaccine. Give example of each with dose and method of administration.
5. Give the physiologic action, use, and dose of salicylate of sodium.
6. Name two drugs used in the treatment of intermittent fever. Write prescriptions showing how they are to be used.
7. What are the therapeutic uses of nitroglycerin? Give its dose.
8. Describe the action and state the dose and uses of mild chloride of mercury.
9. Give the composition, therapeutic use, and dose of Dover's powder.
10. Name the principal narcotics, giving dose of each preparation. In what conditions are they indicated?

ANSWERS.

ANATOMY.

1. *Structure of prostate gland.* "The prostate is a compound tubulo-alveolar gland whose ducts open into the prostate portion of the urethra. Smooth muscle fibers not only surround the organ, but interlace radially toward its center, forming a network in whose meshes the glandular parts are located. Areolar tissue and blood-vessels accompany the muscle tissue. The alveoli of the glands are lined by simple columnar epithelium, which sometimes show two rows of nuclei. These alveoli contain a serous acid coagulum and usually oval laminated concretions called *prostatic bodies*. The latter are more numerous in old men. The numer-

ous excretory ducts unite to form twelve to fifteen collecting tubes which open into the urethra, most of them into the *prostatic sinus*. These ducts are lined by simple columnar epithelium, except near their terminations where it is transitional. The organ dorsal or in front of the urethra is mostly smooth muscle tissue." (Hill's *Histology*.)

RELATIONS OF PROSTATE. *Anteriorly:* Symphysis pubis, anterior ligaments of bladder, branches of dorsal vein of penis. *Posteriorly:* Rectum. *Laterally:* Levator ani. *Base:* Surrounds neck of bladder, seminal vesicles, and vasa deferentia. The apex rests on triangular ligament.

2. "The *larynx* lies in the front and upper part of the neck, being placed below the tongue and hyoid bone and between the large vessels of the neck. It opens above into the pharynx and below into the trachea. It is subcutaneous in the middle line, being covered only by skin and cervical fascia; but laterally it is overlaid by the insertions of the sterno-hyoid and sterno-thyroid, by the thyrohyoid and origin of the inferior constrictor. Is composed of cartilages held together by ligaments, and moved by muscles, the whole being lined with mucous membrane." (*Aids to Anatomy*.)

Structures forming the larynx: Nine cartilages, viz., Thyroid, cricoid, epiglottis, two arytenoids, two cornicula laryngis, and two cuneiform. The thyrohyoid membrane, cricothyroid membrane, thyroarytenoid ligaments, capsular ligaments, hyoepiglottic ligament, thyroepiglottic ligament, and, interiorly, the vocal cords.

3. The *diaphragm* is a musculo-fibrous septum which divides the thoracic from the abdominal cavity; it is fan-shaped; the broad elliptical portion is horizontal, and the crura are vertical. It is attached to the ensiform, to the internal surfaces of the lower six costal cartilages, to bodies and intervertebral substances of first, second, and third lumbar vertebrae. Its openings are: (1) The aortic, transmitting the aorta, vena azygos major, and the thoracic duct; (2) the esophageal, transmitting the esophagus, pneumogastric nerves, and some small esophageal arteries; (3) the opening for the vena cava, transmitting the inferior vena cava, and small branches of the right phrenic nerve; (4) the right crural, transmitting the right splanchnic nerves; (5) the left crural, transmitting the left splanchnic nerves and the vena azygos minor.—*Nerve Supply:* Phrenic, lower intercostals, and sympathetic.

4. THE TENTH CRANIAL NERVE is the pneumogastric nerve. *Superficial origin:* Groove between restiform and olivary bodies. *Deep origin:* Nuclei in floor of fourth ventricle. *Course:* Outward across the flocculus, to jugular foramen through which it passes; here it is joined by the accessory portion of the spinal accessory nerve. As it goes down the neck, it lies in front of the *rectus capitis anticus major* and *longus colli* muscles. It passes in the carotid sheath behind and between the artery and vein. In the thorax the nerve on each side runs a different course. The *right* passes between the subclavian artery and vein, by side of trachea to root of lung, behind esophagus, through esophageal opening in diaphragm to posterior surface of stomach. The *left* passes between the subclavian and carotid arteries, in front of arch of aorta to root of lung, along anterior surface of esophagus, through diaphragm, to anterior surface of stomach. *Distribution* is shown by the names of the branches: Meningeal, auricular, pharyngeal, superior and inferior laryngeal, cardiac, pulmonary esophageal, and gastric.

5. In a cross-section at middle of humerus, will be severed: *Muscles:* biceps, coraco-brachialis, brachialis anticus, triceps; *arteries:* brachial, superior profunda, inferior profunda; *nerves:* median, ulnar, musculo-spiral, internal cutaneous, musculo-cutaneous.

PHYSIOLOGY.

1. *Leucocytosis* is an increase in the number of the white blood corpuscles in the peripheral circulation.

2. *Application of hydrostatic test, to determine whether a dead infant was born alive:* "Having opened chest, note position of lungs (before respiration they occupy a small space at upper and posterior parts of thorax); their volume (of course increased after breathing); their shape (before respiration, borders sharp or pointed; after it, rounded); their color (be-

fore breathing, brownish-red; after it, pale red or pink); their appearance as regards disease and putrefaction; and whether they *crepitate* on pressure (as they will after respiration). Take out lungs with heart attached, and place them in pure water having temperature of surrounding air. Note whether they float (high or low), or sink (slowly or rapidly). Separate them from the heart and weigh them accurately; then place them in water again, and note sinking or floating, as before. Subject each lung to pressure with the hand, and note sinking or floating again. Cut each lung in pieces and test floating again. Take out each piece, wrap it in a cloth, and compress with fingers as hard as possible, and test floating, etc., as before. The crucial test of *perfect respiration* is each piece floating after the most vigorous compression." (King's *Manual of Obstetrics*.)

3. Glands of the stomach are of two kinds: (1) *Fundus glands*.—These are branching glands with short ducts. Their epithelium is of two kinds. There is a continuous lining of cubical or polygonal cells which show granules in their inner part, the outer part being clear. These are the *principal, central, or peptic cells*. Scattered along the tube are large rounded cells, with a much greater affinity for acid dyes. These are the *parietal or oxyntic cells*, which are supposed to secrete the hydrochloric acid. They lie between the principal cells and the basement membrane. They are surrounded by a network of fine channels opening into a fine canal, which carries their secretion into the lumen of the gland.

(2) *Pyloric glands*.—The pyloric glands are longer, and are more branched than the fundus glands. They are lined by principal cells only. Close to the pylorus the glands may extend through the muscularis mucosae into the submucous coat.

4. *Functions of protein food:* Formation and repair of tissues and fluids of the body. Regulation of the absorption and utilization of oxygen. May also form fat and carbohydrate, and yield energy sometimes.

Functions of carbohydrate food: Production of energy and animal heat by oxidation. Form fats and possibly some proteids.

Functions of fat: Supply of fatty tissues, nutrition of nervous system; supply of energy, and animal heat by oxidation.

Function of salts: Support of bony skeleton, supply of HCl for digestion, regulation of energy and nutrition.

Function of vitamins: Growth and nutrition.

5. *Formation of lymph:* There are three main theories: (1) Ludwig's theory, or the filtration theory, coupled with osmotic changes between the lymph and blood; (2) Heidenhain's theory of lymphagogues; and (3) Starling's theory of the permeability of the capillary walls. The subject is summed up by F. A. Bainbridge as follows: "Lymph formation is not a secretory process, but is brought about by purely physical processes, namely filtration and osmosis; and the factors concerned in its production are (1) the capillary pressure, (2) the degree of permeability of the capillary walls, and (3) the metabolic activity of the tissues. There is no reason to suppose that in health the permeability of the capillaries alters, and therefore the formation of lymph is increased chiefly by variations in the first and third of these factors."

Function of lymph: (1) It conveys nutriment to all cells not directly reached by the blood; (2) in the intestines, it absorbs nutrient material (chiefly fat) and pours it into the blood stream for distribution; (3) it takes certain waste matters to the blood to be later eliminated by the lungs, kidneys, and skin.

6. *Metabolism* is the name given to the sum total of all the chemical changes which take place in living matter. These changes are of two kinds: (1) In which tissues or substances are broken down (*katabolism*); and (2) in which the tissues are built up from the nutritive material derived from the blood (*anabolism*).

7. *Function of the epiglottis:* (1) To overhang the larynx during deglutition, and so prevent the entrance of food and drink into the respiratory passage; (2) to direct the food and drink into the lower part of the pharynx; (3) it modifies the air currents in phonation.

8. *Reflex actions* are involuntary or unconscious movements, due to suitable stimuli. They depend upon

the integrity of the *reflex arc*, which is a complex made up of: (1) A surface capable of receiving an impression; (2) an afferent nerve; (3) a nerve cell capable of receiving and also of sending out impulses; (4) an efferent nerve, and (5) a surface capable of responding to the impulse conveyed by the efferent nerve.

Reflexes are classified as: (1) *Superficial reflexes* are such as can be elicited by stimulating the skin. *Example:* The cremasteric reflex. And (2) *deep reflexes* are such as are elicited by stimulating tendons or muscles. *Example:* The patellar reflex.

In the *cremasteric reflex*, irritation of the skin of the upper and inner part of the thigh causes a retraction or drawing up of the testicle. In the *patellar reflex*, if the tendon of the quadriceps extensor is struck with the edge of the hand while the leg hangs loosely over the other leg, there will be an upward jerk of the leg.

9. *Accommodation* is the power of altering the focus of the eye so that divergent rays are brought together on the retina; this is accomplished by increasing the convexity of the lens.

10. *Heat is produced in the body by:* (1) Muscular action; (2) the action of the glands, chiefly of the liver; (3) the food and drink ingested; (4) the brain; (5) the heart; and (6) the thermogenetic centers in the brain, pons, medulla, and spinal cord.

CHEMISTRY.

1. *Physiological chemistry* is that branch of chemistry which has to do with the composition and changes in composition of living things.

2. *Carbohydrates* were formerly defined as substances of unknown constitution containing carbon, hydrogen and oxygen. The molecule of carbohydrate contained six atoms of carbon (or some multiple of this number), and the hydrogen and oxygen were present in the proportion required to form water. While this definition is not, to-day, scientifically accurate, it suffices to "label" a definite class of compounds containing the sugars and starches.

Hydrocarbons are substances which contain only carbon and hydrogen; such are methane, ethane.

3. *Peptones* are substances produced by hydrolytic decomposition of proteins. During the course of protein digestion, the proteins are split up into proteoses, peptones, polypeptides, and amino-acids.

Peptones are produced, during digestion, by the action of pepsin in an acid medium, and of trypsin in an alkaline medium.

4. The reaction of normal gastric juice is acid, due to the presence of hydrochloric acid.

5. *Hemoglobin* is a protein, found mainly in the blood, where it is the pigment in the red corpuscles; it is crystallizable; it contains a small amount of iron in addition to the elements ordinarily found in proteins. It may be split up (by acids, alkalies, or heat) into globin and hematin. Hemoglobin combines with oxygen, carbon monoxide and other gases. Its function is to carry oxygen to the tissues of the body.

MATERIA MEDICA.

1. *BISMUTH. Official preparations and dose:* Bismuth betanaphthol, dose 8 grains; bismuth and ammonium citrate, dose 2 grains; bismuth subcarbonate, dose 8 grains; bismuth subgallate, dose 8 grains; bismuth subnitrate, dose 8 grains; bismuth subsalicylate, dose 8 grains; bismuth magma, dose 1 fluidrachm; *Bismuth may be administered in powder, or capsules, in milk; and it is also applied locally.*

2. *Three safe antipyretics:* (1) The use of cold water, which should be applied rapidly and followed by rubbing of the skin. Cold sponging, cold pack, or the use of a bath may be the method of application. (2) Antipyrin, dose about 4 grains; it is soluble in water. (3) Quinine, in the form of the sulphate, in powder or capsule, or in solution (with glycyrrhiza to disguise the taste); dose about 5 or 6 grains a day.

3. *Two cardiac sedatives:* (1) Tincture of aconite, dose 5 minims; (2) Tincture of veratrum viride, dose 8 minims.

Two cardiac stimulants: (1) Alcohol, dose one ounce of spiritus frumenti; (2) Aromatic spirit of ammonia, dose one dram in a little water.

Two cardiac tonics: (1) Citrated caffeine, dose 5 grains; (2) Strychnine sulphate, dose 1/40 grain.

4. "A *serum* is a product obtained by injecting into an animal, usually the horse, a culture (e.g. Diphtheria) or the toxin from a culture (e.g. Streptococcus) of the organism. Serums may be subdivided into—(a) *Antitoxic serums*, such as Diphtheria and Tetanus, which are obtained by injecting filtered cultures into the animal used to provide the serum. (b) *Anti-bacterial serums*, such as Anti-Streptococcus and Anti-Gonococcus, in the preparation of which unfiltered cultures are used. Serums are usually injected in the flank or between the shoulder blades, the skin having previously been cleansed and the syringe carefully sterilized. Cases are on record where they have been given intravenously with normal saline solution and also per rectum.

"A *vaccine* is a finely divided suspension of killed cultures of a microorganism which is injected directly into the human subject. The object is to stimulate the individual to elaborate his own antibodies, which results in increased resistance to the ravages of bacterial infection. Vaccines are of two kinds—(a) *Autogenous*—prepared from the organism isolated from pathological material taken from the patient. (b) *Stock prepared* from virulent cultures of the organism, isolated from other cases of similar bacterial origin. Vaccines are administered by subcutaneous injection by means of an all-glass hypodermic syringe. The site of injection may be the flank, thigh, shoulder, or back. The skin is first sterilized by a pledget of cotton wool saturated with a suitable antiseptic, e.g. lysol.

"Briefly, the difference is that with a serum the opposing influence to the toxins is produced outside the human body, while with the vaccine it is produced inside and the degree of immunity conferred is greater with the latter than the former. It should also be noted that the dose of a serum is much higher, from the standpoint of the amount of fluid injected, than in the case of a vaccine. With the former the dose usually ranges from 10 c.c. to 50 c.c., while with the latter it is, as a rule, not more than 1 c.c." (*Holland's Pharmacy Handbook.*)

Antidiphtheritic serum, average dose 1,000 units as a prophylactic, and 10,000 units for curative purposes, injected into the loose subcutaneous tissue of the back or abdomen.

Typhoid vaccine, given subcutaneously in the arm, 500 million bacteria at the first injection, and two further injections at intervals of 8 to 10 days of one billion bacteria.

5. *Sodium Salicylate. Action:* Antiseptic; irritant; strongly cholagogue; antipyretic; diaphoretic; diuretic (markedly increasing the excretion of uric acid). In exceptional instances skin eruptions are caused, and in some individuals a train of symptoms analogous to those of cinchonism, and designated as *salicylism*, results from the use of salicylic preparations.

Uses. Externally, as antiseptic and stimulating applications and for the checking of abnormal perspiration; also in parasitic and other skin diseases. Internally, rheumatic fever (in which this drug seems to act as a specific); gout; migraine; sciatica; diabetes; cholelithiasis." (*From Wilcox's Materia Medica.*)

Dose:—15 grains.

6. *Two drugs used in treatment of intermittent fever:* Quinine and arsenic.

R. Quinina sulphatis 5v
Acidi sulphurici q. s.
Aque q. s. ad 5iv

Misce et Signa: One teaspoonful to be taken two or three hours before the attack is expected, and then two or three times a day.

R. Masse ferri carbonatis 5vj
Arseni trioxidi gr. j
Misce et fiant pilule numero xx

Signa: Take one pill two or three hours before the attack is expected, and then three times a day.

7. *Therapeutic uses of nitroglycerin:*—It is indicated in angina pectoris, cardiac dyspnea, chronic nephritis, with high tension pulse, vomiting, epilepsy, hiccup, seasickness, asthma, and other spasmodic disorders.

Dose:—Spirit of nitroglycerin, one minim.

8. "*Calomel* is a white, odorless, tasteless powder, insoluble in all ordinary menstrua. The dose is from 1/10—10 grains. Calomel is used internally as a cathartic, as a diuretic, as an antiplogistic, and as an anti-

syphilitic. Externally it is employed as a stimulant, desiccant, and antiseptic.

External Use.—Zinc ointment to which calomel (5-15 gr. to the ounce) has been added makes an excellent application in subacute and chronic eczema. A dusting-powder composed of equal parts of calomel and zinc oxide is effective in venereal warts. Calomel is also efficacious in corneal ulcers and phlyctenular conjunctivitis when there is not much ciliary irritation. It should be flicked into the eye by gently tapping a camel's-hair brush loaded with the powder.

Antiphlogistic.—Some practitioners believe that calomel is of service in limiting fibrinous exudation in inflammatory diseases of the serous membranes. For this purpose it has been much used in pleurisy, meningitis, iritis, and pericarditis, but its beneficial effects are very doubtful.

Antisyphilitic.—Calomel has been used internally to combat syphilis, but the protiodide and the bichloride are decidedly preferable, since they do not induce salivation so quickly. It is a suitable preparation, however, for volatilization when the patient is to be treated by fumigation. Some surgeons have recommended deep injections of oily mixtures of calomel in syphilis, but grave symptoms have occasionally resulted from its use in this way." (Stevens' *Modern Materia Medica*.)

9. *Dover's powder* is Pulvis ipecacuanhæ et opii. It contains one part of ipecac, one part of opium, and eight parts of sugar of milk. The dose is from 5 to 12 grains. It is used for its diaphoretic effect, and in colds.

10. *Narcotics* are classified (by Bastedo), as:—(1) General anesthetics; (2) Intoxicants; (3) Hypnotics; and (4) Antihysterics. The general anesthetics are:—Ether, chloroform, nitrous oxide, ethyl chloride, and magnesium sulphate. The dose of ether by mouth is 15 minims, of Hoffmann's anodyne, one dram; the latter is used as a carminative and reflex stimulant; to relieve angina pectoris and allied cardiac disturbances; to relieve dyspnea; to allay hysteria and states of nervous instability; to relieve spasm. The dose of chloroform is 5 minims; spirit of chloroform, 30 minims; water of chloroform, 4 drams. Chloroform is used internally as a carminative, an antiemetic, an antihysterical and cerebral sedative. Whiskey and brandy are mostly employed to prevent or check a cold after exposure; to furnish food and stimulation in depressed conditions and in convalescence from acute illness, as a narcotic or sedative in states of nervousness, restlessness or delirium; as hypnotic in mild forms of insomnia as from mental work or continued nervous strain; in fever; in shock. Hypnotics: Chloral hydrate, dose 15 grains; used as a hypnotic, as a circulatory depressant in high arterial tension, chronic nephritis or arteriosclerosis. Sulphonal, dose 15 grains; veronal, dose 5 grains; trional, dose 15 grains; adalin, dose 45 grains; urethane, dose one dram; hedonal, dose 15 grains; all used in cases of insomnia, where the wakefulness is not due to pain; paraldehyde, dose 30 minims. Bromides, in doses of 10 to 30 grains, for nervousness and restlessness, to allay pain, to check vomiting, to prevent convulsions, to check spasmodic nervous affections, to quiet the reflexes. Opium or morphine may be used to stop vomiting, to check peristalsis, to quiet a nervous heart, to lessen pain, to check cough, to compel quiet and sleep. (From Bastedo's *Pharmacology and Therapeutics*.)

Benefactors of the French Academy of Medicine During the Century of Its Existence.—The usual act of the benefactor is to establish a fund for a prize essay. Portal, the first president, left in 1833 the sum of 12,000 francs for a prize in medical anatomy. Others have made various gifts and bequests, the largest by Mme. Ernesti, née Bader, daughter of a medical man, who in 1901 left the institution a legacy of 1,100,000 francs, her entire fortune. In 1877, Demarquay gave a fund of 100,000 francs to improve the installation of the Academy. In 1902 the Government awarded the great sum of 463,000 francs for the new building, and it is believed that this beneficence on the part of the State to a private body of citizens is unique. The total number of benefactors to date is nearly 80 and the revenues from the individual gifts run all the way from 120 francs to 130,000 francs.—*Le Presse Médicale*.

Miscellany.

NEW BOOKS AND OLD.

By JOHN RUHRÄH, M.D.,

BALTIMORE, MD.

III. THOMAS MUFFET.

FOR the second time in the past fifteen years it has been my pleasure to have in my hands a copy of "Health Improvement: Or Rules Comprising and Discovering the Nature, Method, and Manner of Preparing all Sorts of Foods Used in this Nation," by Thomas Muffet. This is a rare treasure, not because it adds anything to the sum total of human knowledge, but because of the fact that Muffet, who was a considerable traveler, collected in his travels and from the various authors of earlier times, a lot of quaint material dealing with the subject of dietetics and he is, as far as I know, the first English physician to write a book devoted solely to this subject.

Muffet lived in the time of Shakespeare. A London lad of Scotch descent, whose father was a citizen and haberdasher of London, he was, at the age of sixteen, matriculated as a pensioner of Trinity College, Cambridge, but in 1572 changed to Caius College, where he was graduated as a bachelor of arts. During this period he also studied medicine under Thomas Larkin and John Caius, the latter mentioned in his "Health Improvement." He numbered among his friends and fellow students three boys who became distinguished as physicians: Peter Turner, Timothy Bright, and Thomas Penny. In 1576 he was expelled from Caius College because he chose to proceed as master of arts from Trinity and later he went abroad and received his degree of doctor of medicine at Basle in 1578. Whilst at Basle he was a student of Felix Platter and Zwinger. The following year he traveled in Italy and Spain and studied the silk industry, which he afterwards described in a long poem. The next year he was at Nuremberg and Frankfort, and during his entire life he seems to have been devoted to travel, as he mentioned that he visited Denmark, High Germany, Holland, Bohemia, Switzerland, and Wales.

On his return to England he was incorporated doctor of medicine at Cambridge and the same year, 1582, he visited Elsinore in Denmark. On this occasion he accompanied the diplomat who carried the Order of the Garter to the King, and so was able to partake of the royal hospitality. He mentions that the State banquets last from seven to eight hours. He practised at Ipswich and later on lived in London. In 1588 he was made a fellow of the Royal College of Physicians and one of the censors the same year. The latter part of his life was spent as a pensioner of the Pembroke family, and through the influence of the early Pembrokes he was elected a member of Parliament from Wilton in 1597.

Muffet was one of the earliest Paracelsians, or chemical sect, in England, and with John Herter was one of its chief exponents. His first publication was a defence of the use of chemical medicines. Like many physicians, he was interested in natural history, and he wrote a volume concerning insects, which was printed in 1634, and subsequently translated into English and published in 1658.

During his undergraduate course he was poisoned

by eating mussels, and he refers to shellfish, and chronicles the event in "Health Improvement," as follows:

Only Oysters of all fish are good raw (yet he was no Coward that first ventured on them).

For Diogenes died eating raw fish and Woolmer (our English Pandereus) digesting iron, glass and oyster shells, by eating a raw eel was overmastered.

Mussels were in credit, but amongst the poorer sort; till lately the lily-white *mussel* was found out about Romers-Wall, as we sail between *Flushing* and Bergen-up-zon, where indeed in the seat of Summer, they are commonly and much eaten without any offence to the head, liver or stomach; yea, myself (whom once twenty mussels had almost poisoned at *Cambridge*, and who have seen sharp, filthy and cruel diseases follow the eating of English mussels) did fill myself with those mussels of the Low Country, being never a whit dis-tempered with my *bold* adventure.

The status of dietetics in his day seems to have been much as it is now, as he says:

So how in our Daies the name Diet seems but a scarce-crow to the unwiser sort, who think it best diet, keeping no diet at all saying (as Will Somers said to John Rainsford) drink wine and have the gout, drink no wine and have it too.

Muffet was interested in the question of the value of odors in medical treatment and thought that they had considerable value, as he states: "The very smell of physick cures many." He considered the following observation of great value in establishing the effect of odors as preventatives against infectious diseases:

But here a great question ariseth, whether sweet smells correct pestelent aire, or rather be as a guide to bring it sooner to our hearts? To determine this question I call all the dwellers in *Bucklers berry* in London to give sentence: which only street (by reason that it is wholly replenished with Physick, Drugs and Spices, and was daily perfumed in the time of the plague with punding spices, melting gums, and making perfumes for others) escaped that great plague brought from Newhaven whereof there died so many, that scarce a house was left unvisited.

His chapter on unusual articles of diet and abnormal longings contains much interesting, if questionable, material. A short extract from it will give a very good idea.

The Sudanes desire to feed on lice, which a Muscovite abhors so to kill; lest unnaturally or unwittingly he slay his own blood.

It were strange to believe (yet *Fernelius* writes it for a truth) how a nobleman of *France* found a great sweetness in quicklime, then in any meat beside, refreshing his stomach and hurting no inward part with the continued use thereof. Others feed greedily on rags of woollen cloth and wall-morter. And *Anatus Lusitanus* remembereth a certain young maid of twelve years of age, who did usually eat stones, earth, sand, wool, cotton and floss; esteeming their taste and substance better than the finest and tenderest partridges. *Marcellus Donatus* saw a girle so longing after Lizards and Neayts, that she would hunt after the one in the Gardens, and after the other in houses with a bough in her hand as a cat would a mouse, and eat them without hurt.

Albertus Magnus (as *Caelius* reporteth) saw another wench in *Collen*, but three years old hunting as delightedly after all sorts of spiders, with which meat she was not only much delighted but also exceedingly nourished. Yea Doctor *Oethaeus* telleth a story of a certain farmer in the country of *Hirsberg*, that feedeth chiefly on potsherds finely beaten batling no less with them than *Marriners* do with eating biscuit. And *Joachim Comerarius* (my dear and learned friend) reporteth a certain girl in *Norimberg* did eat up her own hair, and as much as elsewhere she could get; neither could she be persuaded by her parents or friends, to think it an unpleasant or an unwholesome meat.

Of the quantity that can be eaten at one time, the following quotation is not without interest, especially in this day when there has been an almost total passing of these enormous eaters:

Of this crue was *Maximus* the Emporer (like our old *Abbey Lubbers*) ate till he sweat; yea *Sabellius* affirmeth that his one days sweat gathered up in goblets, did amount to the measure of six sectaries.

And though *Aurelianus* the Emporer fed moderately himself, yet he exceedingly loved and honored a great Gourmand, who usually at a meal did eat a Hogg, two weathers, and a whole brawn, drinking upon it a whole firkin of wine poured down his throat through a funnel.

Clodinus Albinus (commander of the Romans in *France*) is registered to have eaten at one sitting 500 figs, 100 peaches, 10 musk melons, 20 pound weight of *Raysins* of the Sun, 100 snites, 10 capons and 150 great oysters.

Of the length of time spent at meals, *Muffet* gives a personal experience:

Switrigalus, Duke of *Lithuanna*, never set fewer than six hours at dinner, and as many at supper; from whom I think the custom of long sitting was derived to *Denmark*; for there I remember I sat with *Frederick*, King of *Denmark*, seven or eight hours together at one meal. But of all long sitters at table, farwell *Hugutio Fagiolanus* who (as *Petrarch* reporteth) lost both the city of *Pisa* and *Lukes* at one Dinner, because he would not arise (although a true alarm was given) to repel the enemy till his dinner was fully ended, which was usually protracted two or three hours.

One of the most interesting parts of the whole books are his observations on milk and his words of advice on the "Chusing of a Good Nurse," are unsurpassed:

The nurse must be young, clean of skin, of a kindly smell, pure complexion, good temperature, wholesome and moderate diet, much sleep and little anger, neither too idle nor too toiling, no wine bibber, no eater of hot spices, no ordinary wanton, and void of all diseases; such a nurse is sooner wished for than found, yet such a one is to be chosen for sound children or sick Persons, lest drawing corruption in so fine a meat as milk is, our consumptions be increased so much the more, by how much poison given with drink is more dangerous.

Furthermore care is to be taken of their health, that give us milk; for as an unclean pocky nurse (which woful experience dayly proveth) infecteth most sound and healthy children, so likewise a clean, sound and healthy nurse recovereth a sickly and impotent child. Nay (which is more no man can justly doubt, that a child's mind is answerable to his nurse's milk and manners; for what made *Jupiter* and *Aegystus* so lecherus, but that they were chiefly fed with goat's milk? What made *Romulus* and *Polyphemus* so cruel but that they were nursed by she-wolves? What made *Pelias* (*Tyrus* and *Neptune's* son) so brutish but that he was nursed by an unhappy mare? Is it any marvel also, that *Giles*, the *Abbot* (as the *Saint-Register* writeth) continued so long the love of a solitary life in woods and deserts, when three years together he sucked a doe? What made *Dr. Cajus* in his last sickness so peevish and so full of frets at *Cambridge*, when he sucked one woman (Whom I spare the name) froward of conditions and of bad diet; and contrariwise so quiet and well when he sucked another of a contrary disposition.

Muffet was no vegetarian. He believed in good living, and on the question of abstaining from meat as an article of food, he adorns his work with a tale pointing a moral.

Thus much said *Baldwin*, Archbishop of *Canterbury*, of whom *Rainulphus* writeth this story. When *Baldwin* was chosen Archbishop of *Canterbury* he swore that from the time of his installment to his dying day,

he would never eat flesh; whereby his body so decayed that he fell into a consumption: an old woman meeting him on the way as he was carried on a open Horse-litter, called him a liar to his face; whereof being reproved by some of his followers, why (said she) do you rebuke us? doth he not lie, for saying that he never ate flesh since his installment, when his own face sheweth that he surpassed the savages in eating his own flesh? for indeed by the superstitious observance of his vow he had become an anatomie and lived as a cypher among men.

Muffet also wrote a poem on the silk worm which has the following title page:

The
Silkworms, and
their Flies:

Lively described in verse, by T. M.
a Countie Farmer, and an ap-
prentice in Physicke.

For the great benefit and enriching of England
Printed at London by V. S. for Nicholas Ling, and
to be sold at his shop at the West ende of
Paules. 1599.

From Hironimus Vidas, Bishop of Alba, he borrows the story of Venus, seeing Pallas and the other nymphs and goddesses taught by Saturn how to clothe themselves in lawn and cambric:

Fretted to see herself and boy new borne,
Left both to heaven and earth an open scorn.

She cried to Jove, offering to teach him the art of love, but he refused her aid. In order to brew trouble, Venus chose Phyllira, the daughter of Oceanus, and:

Straight lodged her son in fair Phillyraes eyes.
And caused him thence to dart up such a fire,
As he had consumed the very starres and skies,
Yea melted Saturn's wheels with hot desire.

Saturn responded promptly and sought to woo the maid, but:

He loved, she lothed, he liked, she disdained,
He came, she turned, he pressed, she ranne away.

Saturn then sought out Venus and offered her the richest clothing for the secret of her art, and to requite her:

He sent a Napkin ful of little seeds,
Tane from the tree where *Thisbes* soul did light,
To make herself and boy farre braver weeds,
Than *Pallas* had, or any of the sev'n.

With this gift of the mulberry tree, he sent along the art of weaving.

The first part of the poem ends with the following Kiplingesque appeal to the English people:

Dull witted dolts that huge things wonder at,
And to your coast coast daily from your ile
To see a Norway whale, or Libian Cat,
A carry-castle or a crocodile,
If lean Ephesian, or the Adberian fat
Lived now, and saw your madness for a while,
What streaming floods would gush out from their
 cries,
To see great Wittols little things despise.

The second part of the poem deals with the silk-worm and its care. The mulberry tree on which these worms feed is thus described:

I leave to tell how she doth poison cure
From adders goare or gall or lizards got,
What burning blaines she heales and sores impure,
In palat, jawes, and al enflamed throte,
What canckers, hard, and wolfs be at her lure,
What Gangrenes stop that make our toes to rotte:
Briefly, few greifes from Panders boxe out-flew,
But here they finde a medicine, old or new.

Muffet noted the infectiousness of the silkworm disease and directs the separation of the dead and sick:

Wisdom commands to part the dead and sick
Lest they infect the faultless and the quick.

He compares their sleep to the epidemic sweat:

Oft shall thou see them careless of their meate
Yea overtane with deepe and heavie sleepe,
Like to the strange and Epidemian Sweate,
When deadly slumbers did on Briton creep.

But I must make an end. Few of my readers will ever come across either of these books, but if you should, do not scorn them, they are full of interest. I have scarcely scratched the surface of what they contain. They are the legacy to the medical profession from one in the past, a gentlemanly physician, scholar, a devoted student of natural history.

11 EAST CHASE STREET.

Chemistry and the Problem of Feeding the Germans During the War.—A volume having recently appeared on this subject, the editor of *La Presse Médicale* for October 20, 1920, xxviii, 76, publishes a short digest thereof. Before the war Germany had been stocking up on cattle, cereals, and fertilizers, evidently in anticipation of a blockade. The stocks of bran and oil cakes were especially large. It was necessary to provide an abundance of food for cattle as well as fertilizers to safeguard farm and dairy production. A clash was foreseen between nitrogen intended for peace activities and nitrogen for munitions and explosives, for the same substances were used for both purposes. The beginning of hostilities would shut off most of the imports, and the problem of substitute foods would be active at an early period. Meat must be replaced by vegetables in human diet because of the ultimate shortage. The so-called mineral yeast was prepared on a large scale. This concentrated food was rationed at 50 daily grams a head. Some of the nitrogen of this yeast was extracted from the air. To meet the inevitable shortage of fats, oil-bearing seeds were planted in all of the conquered territory. The yield, however, was scanty and was eked out by oil extracted from spoiled meats and fish, animal cadavers, slaughter-house waste, etc., and corresponding vegetable substances which otherwise would have gone to waste. Attempts to make a fat-containing yeast were not successful. The sources of carbohydrate were well known during the war and need not be enumerated here. The problem of the alimentation of cattle brought out the fact that the nitrogen of ammonia could be made to supplant a certain amount of protein nitrogen. Thus ammonium acetate could replace a third of the albumin of the diet in milch cows without prejudice to the milk. The herbivora, unlike mankind, can utilize gelatin. For the ballast which is so very necessary to ruminant animals straw was largely utilized after first softening it with lye, and extra mass was given by the injection of compressed air. The cattle ate the prepared straw but it was not a complete success on account of the two per cent. of soda lye addition. Attempts to prepare a sort of diet carbohydrate from straw and wood by the addition of acids produced too much furfural and other toxic aldehydes.

JAUNDICE.*

By JOHN B. DEEVER, M.D.,
PHILADELPHIA, PA.

A REVIEW of the various pathological conditions which are associated with jaundice establishes the fact that this is not a clinical entity *per se*, but a symptom. Jaundice, as is well known, may occur in conjunction with obstruction of the larger bile passages by gallstones, cicatrices, neoplasms; also it may result from obstruction of the bile passages within the liver, due either to infiltration of a primary or to a metastatic tumor into the liver parenchyma; or to a localized inflammatory process. And even in certain infectious conditions that have no apparent connection with the liver, jaundice may occur, as in pneumonia, typhoid fever, yellow fever, malaria, etc. Toxic poisons likewise often produce a yellow pigmentation of the skin, such as arsen, phosphorus, and the like. Icterus neonatorum is a well-known type of jaundice traceable to physiological conditions, and finally the psychic element is called into play in what is known as emotional jaundice.

The most common type of jaundice, however, is that in which absorption of bile is due to obstruction of the common bile duct by stone; less frequently, as in catarrhal and infectious jaundice, bile absorption takes place in the liver without gross duct obstruction; while in the hemolytic type of jaundice the discoloration of the skin is primarily due to disintegration of the red blood corpuscles by which hemoglobin is set free. For a long time this last type of jaundice was supposed to be independent of the bile-manufacturing function of the liver but extended experimental and clinical studies, especially by Minkowski, Naunyn, Rost, Brulé, and an army of others have demonstrated a close relationship between hemolytic jaundice and the behavior of the liver cells. Rost, in fact, finds an analogy between the jaundice due to obstruction and hemolytic jaundice. As a result of the diminished resistance of the red blood corpuscles, which constitutes the basis of hemolytic jaundice, the gallbladder loses its color and its walls become thickened, so that bile fails to be excreted by the pressure action of the liver, and owing to its accumulation in the liver, it is forced into the lymphatic system and the blood stream, with icterus as a result. Other authors have confirmed this theory by the observation that in hematogenous toxic icterus a similar rupture of the capillaries of the bile passages—bile thrombi—takes place as in obstructive

jaundice, so that the thrombosis of the bile capillaries may be regarded as the immediate cause of hemolytic jaundice (Rost). On the other hand, Brulé and other French authors develop a theory of descending infection and the lesion to the liver cells as the active factors in jaundice. They contend that the infecting organisms primarily enter the blood and in the course of elimination produce the injury to the liver parenchyma and the ducts. In all varieties of the disorder the lesions which lead to bile stasis, they believe to be of secondary importance. Brulé insists that the obstacle to the course of the bile lies upward in the small bile ducts and on the same level as the hepatic cells. The latter are seriously affected in numerous cases of severe infectious jaundice as well as in toxic jaundice and in icterus due to cirrhosis of the liver. Pathologically the relationship between jaundice, cholecystitis, and interstitial hepatitis has been frequently observed by Dr. Reiman, the pathologist at the Lankenau Hospital, during the past five or six years, and reported by him in a paper read before the College of Physicians of Philadelphia in 1919. In the examination of gallbladders extirpated with some liver substance attached he has frequently noted the existence of interstitial hepatitis. This fact is confirmed by Ewerts Graham and supported by the interesting experimental work of the latter by which he demonstrates that by the close lymphatic relationship between the gallbladder and the liver there is established a vicious circle of infection between the two organs. The protection of the liver, the most important organ of metabolism, therefore, forms an additional argument in favor of cholecystectomy in cases of cholecystitis.

To return to our subject. The liver cells are also probably affected in the milder types of catarrhal jaundice, except that in these the lesions are slight and easily recover. This can be demonstrated by special tests for determining the presence of bile retention by examination of the urine, the feces, and the blood. Hoover and Blankenhorn have devoted special attention to the study of the bile elements in the plasma in what is known as dissociated jaundice, a favorite subject of discussion among French authors. As its name implies, the term refers to the dissociation of the bile salts and pigments in the plasma. By the use of collodion sacs together with spectroscopic analysis they have been able to demonstrate that the bile salts formed within the liver may be sent on separately into the blood, although they are not certain that the same holds good for the bile pigment. At any rate they have demonstrated the existence of dissociated jaundice of hepatic origin. For the sake of clearness they propose the term "complete jaundice"

*Read before the Iowa Section of the American College of Surgeons, Des Moines, Iowa, February 28, 1921.

for the cases in which both bile pigment and salts are present in the blood, and "hepatic dissociation jaundice" when bilirubin or bile salts are found separately in the blood, "due to one or the other of the bile elements being separately shunted into the blood stream"; while hemolytic jaundice indicates the presence in the blood of bilirubin without bile salts, when bilirubin is formed extrahepatically. In cases of complete cholemia of hepatic origin the pigment is present in the blood but not the salts. In these the latter have been yielded to and eliminated by the kidney, while the absorbed bilirubin has adhered to the plasma. For this they use the term "renal dissociation icterus." While this theory is probably correct, the analytic methods of these authors have been criticised. Nevertheless their results are of interest and without doubt indicate a fruitful field of investigation.

In its clinical manifestations jaundice may be painless or it may be accompanied by pain, fever, chills, and all the indications of a severe illness. The most frequent type seen is the mild catarrhal painless type associated with moderate digestive disturbances, loss of appetite, constipation, nausea, sometimes also vomiting, mental indifference, sluggishness, together with gradually increasing icteric hue of the skin and sclerae, dark urine and clay-colored stools. The absorption of bile here is probably due to some obstruction to the smaller radicles of the liver, that is a cholangitis, very often a mucous obstruction. This will generally yield to medical treatment but a recurrence is to be expected. When the condition is more acute, absorption is in all likelihood due to calculous obstruction of the bile passages. This type is, as a rule, characterized by sudden onset of severe colicky pains, sometimes radiating to the mid-back and to the right shoulder blade, accompanied by nausea and vomiting, followed in a few days by the typical icteric color of the skin and sclerae. If the calculus is in the gallbladder there is a spasmodic contraction which causes the pain, and which also allows a little bile to escape. While this type of jaundice and its concomitant symptoms will also subside under medical treatment, recurrence is practically certain and the damage to the tissues no less certain. After a second attack the question of surgical interference should be seriously considered, for the interval operation in these cases, it is needless to say, is much safer than when undertaken during an acute attack. Moreover, the clinical differentiation between jaundice due to an inflammatory process and that to malignant obstruction can scarcely ever be made. While the duodenal bucket and some other tests perhaps will indicate whether or not bile is entering the duodenum and also may be useful in estimating the sufficiency or otherwise of the pancreatic ferments, they do not aid us in detecting the presence of malignancy, which is the cause of jaundice in about 15 per cent. of the cases. In a considerable percentage also the pancreas is involved and in not a few carcinoma of the head of the pancreas is the underlying cause of the obstruction. It has been estimated that 50 per cent. of the cases of obstructive jaundice due to cancer are from cancer of the liver and the other 50 per cent. from cancer of the pancreas or of the gall bladder and ducts (W. J. Mayo). Even with the abdomen

open it is not always possible to tell whether the hardening of the pancreas which so often accompanies disease of the gall bladder is due to inflammation or to malignancy.

In hemolytic jaundice the symptom is not due to obstruction but is acholuric in character. It is usually associated with enlargement of the spleen and anemia, the latter often paroxysmal and of varying intensity. The red blood cells are diminished in number and in resistance to hypotonic salt solution, the urine usually shows excess of urobilin and urobilinogen. Two types of the disease are described, a congenital and a familial. In the congenital form jaundice may be present from childhood and the subject otherwise be in perfect health, the full picture developing as the years go on. The familial type is the more common of the two. Various members of one family present a similar history of jaundice and the associated syndrome. Cases are recorded, however, in which while one member presents the complete picture, the others show only jaundice and the splenic enlargement, without either the typical blood picture or the excess of urobilin and the urobilinogen in the urine.

According to some authorities, the behavior of the red blood cells enables the differentiation to be made between a hemolytic and a non-hemolytic jaundice. That is to say, in the former, the resistance of the red blood cells is decreased and in the latter it is increased. But Brulé believes the increase is not sufficiently constant to be reliable. Closely allied to this type of jaundice is that associated with cirrhosis of the liver, known as Hanot's disease. In this also the spleen is enlarged and there is anemia and jaundice with exacerbations.

Hemolytic jaundice with splenic enlargement is of special interest to the surgeon owing to the very satisfactory results that are being obtained by splenectomy in its treatment. The rationale of the procedure is indicated by the experimental work of Whipple, McNeely, and others, who show that bilirubin is not exclusively formed in the liver, but may be elaborated by the endothelial cells elsewhere in the body, for example the spleen, the kidneys, and the bone marrow. The primary cause of jaundice therefore is not always the liver but may be found in other organs. Here again, the removal of the spleen acts as a protection to the liver whose metabolic function is of such vital importance to the body economy.

Finally there is the surgical type of jaundice following operation on the biliary passages, either as the result of an extension of infection or from injury to the hepatic or the common duct. In the former the jaundice is painless and in most instances is due to an infective cholangitis, the result of extension of inflammation from the gallbladder bed, after cholecystectomy, or of inflammation extending up the hepatic duct, or more often the common duct. In either case the cause is the liberation of infection which is then carried by the blood stream or by the lymphatics; or infection may possibly have been forced into the cystic duct and by this route have reached the hepatic or the common duct. Jaundice resulting from operative injury to one or the other of these ducts is probably the most difficult to deal with, and I regret to

say that it is a type I am too often called upon to correct. While it is perhaps not always avoidable, this accident should not occur if the anatomical landmarks are recognized and the operation conducted without undue haste. Occasionally I believe it results from the attempt to control bleeding from the divided cystic artery when the ducts are accidentally grasped by the hemostatic forceps.

A type of jaundice which is not described in textbooks, so far as I know, was recently seen at the Lankenau Hospital. A young woman applied for admission on account of a peculiar yellowish hue of the face and a train of indefinite symptoms, the most pronounced of which was an apparent nausea. On examination, the sclera and skin elsewhere on the body were remarkably clear, and no cause for the abnormal pigmentation could be found until the nurse took the patient into the washroom and washed off the iodine with which she had painted her face in order to gain admission to the hospital. Removal of the patient to her home was the radical operation performed in this case.

1634 WALNUT STREET.

SOME REMARKS ON TONSILLECTOMY AND ADENOIDECTOMY.*

By LESTER MEAD HUBBY, M.D.,

NEW YORK.

PHYSIOLOGY.—The tonsils are the most specialized collections of lymphoid tissue in the body, leaving out the spleen. Their function seems to be to act as a barrier to infection, although some believe that they also have an excretory function for the nose and adjacent structures. Until diseased or overcome by attacking organisms they act as a protection, permitting the passage of but few live bacteria. When acutely or chronically diseased both toxins and living bacteria may pass through them into the blood and lymphatics. The mere presence of bacteria on their surfaces or in their crypts is no proof of their pathologic or pathogenic condition. According to Renn the findings of a preponderance of pus cells over lymph cells in the crypts points to inflammatory processes in the tonsils, the examination of course being made when the tonsils are not acutely inflamed.

The Inter-relation of Tonsils and the Vermiform Appendix.—Frankel, and his co-workers, have claimed that there is a close relationship between the tonsil and the vermiform appendix, that histologically they are markedly similar and that the removal of one is liable to affect deleteriously the other.

In 1,004 ear, nose, and throat cases treated by me in the out-patient department of the American Red Cross Military Hospital No. 2 at Paris, in 1917, 1918 and 1919, there were histories of 95 tonsillectomies and 68 appendectomies. Nine tonsillectomies were associated with appendectomies, 86 with no such association, 15 associated with either appendicitis or appendectomy. Of the 68 appendectomies, 9 were associated with tonsillectomies, 39 were associated with some history of attacks of tonsillitis or tonsillectomy, 29 with no

such association, and 59 were not associated with tonsillectomy. Expressed in percentages:

	Per Cent
In 1,004 cases, tonsillectomies (95).....	9.46
In 1,004 cases, appendectomies (68).....	6.8
Tonsillectomies (9) associated with appendectomies....	9.4
Tonsillectomies (86) not associated with appendectomies or appendicitis.....	90.6
Appendectomies (9) associated with tonsillectomies....	15.7
Appendectomies (59) not associated with tonsillectomies....	13.2
Appendectomies (39) associated with tonsillitis or tonsillectomy.....	57.3
Appendectomies (29) not associated with tonsillitis or tonsillectomy.....	42.6

These figures do not bear out any close relationship. Of course lymphoid tissue throughout the body is susceptible to similar toxins and bacteria, so that when the latter are present in the blood they may attack different collections of such tissue at the same time.

Indications for Tonsillectomy.—1. Hypertrophy sufficient to cause mechanical obstruction or interference with the palatal muscles. This is often a difficult question to decide. Some tonsils are not imbedded deeply and are thrust out when the tonsillar pillars are contracted, as during gagging. With the throat quiescent these same tonsils may be little if any obstructive. From the standpoint of the speaking and singing voice any considerable real hypertrophy is a handicap, interfering with the palatal muscles. But tonsillectomy in an adult singer should not be lightly undertaken on account of the psychological and temperamental factors, as well as the interference with their vocation for possibly several months.

2. Manifest pathological condition of tonsils as shown on inspection, the tonsillar crypts large, with gaping openings, infective material being easily expressed therefrom, and microscopic examination of a smear from the crypts showing larger numbers of pus cells than lymph cells (Renn.)

3. History of repeated tonsillar or peritonsillar infections.

4. Cervical adenitis associated with attacks of tonsillitis. The glands near the angle of the jaw are the ones usually attacked.

5. When tuberculous adenitis occurs in this region, it shows that the tonsils have not proved a barrier but a gateway. Therefore the removal of the tonsils should be considered if only for the sake of the removal of this path of tuberculous infection.

6. General or local infections, where there is the slightest suspicion that the tonsils are the starting points, but only during the quiescent stages, *e.g.*, acute or subacute articular rheumatism; arthritides, where the periarticular changes predominate (Crowe); endocarditis; glomerulo-nephritis early stage; appendicitis.

7. In thyroid diseases the tonsils should be carefully examined and even if only slightly involved should be removed.

8. History of frequent colds or attacks of otitis should direct one's attention to the tonsils and adenoids.

Indications for Adenoidectomy.—1. Obstruction in the nasopharynx sufficient to cause mouth-breathing.

2. Any demonstrable growth of lymphoid tissue in the nasopharynx, as it is liable to start inflammatory changes in the nose and ear. Otitis occurring in infants is usually of adenoid origin and should direct attention to the nasopharynx.

*Read at a meeting of the Riverside Practitioners' Society, December 14, 1920.

Contraindications.—1. Diabetes mellitus. 2. Acute rhinitis, tonsillitis or peritonsillitis. Tonsillectomy has been done frequently in these conditions, but the risk of spreading the infection is considerable. 3. Acute infections from the tonsils—rheumatism, chorea, nephritis, endocarditis, etc., during the acute symptoms. 4. Low conditions of nutrition in infants and young children especially, (C. H. Smith). The nutrition should first be raised as much as possible. 5. Cardiac diseases during stages of decompensation. 6. All serious diseases associated with fever. 7. Status lymphaticus. In the male adult, suspect one with broad hips and scanty hair on the body, approaching the feminine type. In the female the hair on the body is also much below the normal, the skin is of unusually delicate texture, and often there are axillary pads of fat, with a scanty growth of hair (Symmers). 8. Hemorrhagic diathesis, until the tendency has been overcome, if that is possible.

Preparation of the Patient for General Anesthesia.—The preceding evening meal should be light, and a mild efficient cathartic should be given before retiring. If no movement occurs the following morning an enema should be given, especially in children. Calcium lactate has not proved to be of value in shortening the coagulation time of the blood. The ideal time to operate is in the early morning. No breakfast should be given and only water allowed. A hypodermic of atropine is given half an hour before the anesthesia. The dosage for a child of three years is gr. 1/250, five years gr. 1/200, fifteen years gr. 1/150. This markedly lessens the secretion of mucus and saliva, making the anesthesia smoother and thus lessening the danger of pulmonary complications.

Local Anesthesia.—If local anesthesia is to be used there need be no reduction in the diet unless there is a strong tendency to gagging, when the last meal can be cut in half or omitted. Ten per cent. cocaine is applied several times to the tonsils, the uvula, and the nasopharynx. The adenoid region is given special attention if the adenoids are also to be removed. Novocaine, 1 per cent., or cocaine, 1/10 per cent., is then injected into the capsular regions of the tonsil, either through the anterior pillars in two spots—one at the upper end, and the other at about the middle of the anterior pillar and both about 2/3 cm. anterior to the pillar's free edge,—or as suggested by Jacob Braun, to use a slightly blunted needle and insert this through the tonsil in three places until the needle reaches the capsule. Then force the needle a few millimeters into the capsular tissues, injecting about one cubic centimeter at each spot. The points of entrance of the needle should be near the anterior pillars. If the solution spurts out on injection the capsule has not been penetrated. The direction of the needle should be outward and backward. Others content themselves with injections just beneath the mucosa of the pillars. Adrenalin is avoided for two reasons,—first, and principally, on account of the subsequent dilatation of the blood vessels, causing more frequent secondary hemorrhages, and second, on account of occasional deaths reported as occurring during its use, said to be due to injecting into a blood vessel.

General Anesthesia.—Ethyl-chloride-ether se-

quence is very satisfactory in children. The former is given by the open chloroform mask drop method until the child is barely under, as determined by the dropping of the arm or the ceasing of counting, talking, or crying, never continuously after the first tendency to snore. Ether is then given by the drop method, using a rubber dam with a small hole for the ether, over the mask when necessary. The anesthesia must be deep enough to abolish the oropharyngeal reflex and is continued during the operation through a hooked tubular mouth-piece extending over the edge of the left corner of the mouth. The ether vapor is forced to the mouth either by the pump or the suction apparatus, or by using a tank of oxygen connected to a bottle of ether, the oxygen and ether vapor is delivered into the mouth. Gas-ether sequence is preferable in adults. Some anesthetists prefer to continue the anesthesia during the operation with chloroform vapor forced through the mouth-piece with a hand or foot pump, as required. If chloroform is used, it must be sparingly, remembering that status lymphaticus occurs most frequently in individuals with lymphoid hypertrophy of the throat and that status lymphaticus is a contraindication to the use of chloroform.

Choice of Operation.—Tonsillectomy as done today can be divided into two distinct methods, the various dissection procedures, and those done with the guillotine.

Dissection Methods.—The removal of tonsils with the finger has been discarded by most operators on account of the unnecessary amount of trauma and resulting inflammatory reaction. The ability easily to recognize the tonsillar tissue limits with the finger made the operation attractive. The partial separation of tonsils from their pillars and fossæ with blunt, semi-blunt or sharp instruments, followed by snaring through the pedicles, is the operation of choice with many laryngologists. Compared with the various guillotine methods there is bound to be the opening up of more avenues of infection into the various tissue planes surrounding the tonsils, more tearing and bruising and therefore greater resulting inflammatory reaction. The truth of this assertion can be demonstrated readily by trying the two methods on the same patient. On the completion of the two operations, on the side operated on by the guillotine method the tonsillar pillars appear uninjured and standing in their normal position unstretched; while on the other side there is more bruising of the pillars, which appear to be stretched and not as perpendicular as those of the other side.

The Guillotine Operations.—On the advent of the dissection methods, this operation fell into disrepute owing to the fact that the instrument in most cases was not accurately applied around the tonsil. The result was a tonsillotomy and not a tonsillectomy. Sluder, in 1911, changed all this by his new method of applying the guillotine. He reversed the application of the old McKenzie tonsillotome, scooped up the tonsil from its bed until it formed a mound just above the junction of the two tonsillar pillars, gently manipulated the tonsil into the ring of the guillotine where necessary, dragged the tonsil bodily forward until the fenestrum of the instrument was opposite the slight projection (alveolar prominence) below the last molar tooth of

the mandible, applied the instrument strongly against this projection, rammed the blade through the mucous membrane and loose capsular tissues, and drew out the tonsil from the slight remaining attachments. The blade of the guillotine was made rather dull with the object of crushing off the tonsil and thus minimizing hemorrhage. With young children the method is excellent, but with tonsils that have thickened capsules it would seem that too much force had to be used in tearing the tonsil from its attachments. To overcome this, Sluder invented a lever which could be attached to the guillotine in order to more thoroughly cut through the capsular attachments before tearing out the tonsil. He advocated removal of a slight edge of the anterior pillar. This is entirely unnecessary and can be avoided by watching the cutting blade as it approaches the tonsil, shifting the direction of the shaft of the instrument so as to cut directly behind the anterior pillar. Beck suggested removal of the tonsil as soon as the latter was manipulated through the fenestrum without drawing the tonsil forward to the alveolar eminence. Considerable pressure has to be used with the finger in keeping the tonsil thoroughly through the fenestrum, so that it is easy to tear through this spot. The use of gloves lessens this materially. This procedure of Beck is often successful, but the percentage of failure is usually higher than by the method of pressure advocated by Sluder. A more satisfactory method in the Sluder operation is to use a sharper blade, cutting through slowly. This decreases the forcible tearing and the slightly greater hemorrhage can be readily controlled.

There are three main modifications of Sluder's method: 1. The use of a snare surrounded by a strong ring, the instrument being applied in a fashion similar to that of Sluder. The Beck, Schenck, and Baum instruments are examples. The Beck and Schenck instruments are rather hard to handle, but when the technique is mastered the results are ideal. The Beck and Schenck instruments, by using two, one for each tonsil, can be left in place as long as seems desirable, thus having a bloodless field during the application of the second snare. Dr. Harry L. Baum has devised a very satisfactory snare, shaped like the Sluder tonsillotome. It has a strong trigger grasp for pulling the snare and also a threaded wheel, so that the enucleation can be done as slowly as desired. It is easier to handle than that of Beck, and the wire is drawn from the large fenestrum through a groove into a slightly contracted space, bending the loop very little, so that it can be used for several operations without replacing the wire. Baum uses the Beck technique. As the wire approaches the anterior pillar he pulls gently away from the pillar so as to avoid grasping any portion of it. Some shreds of tissue are drawn into the groove, so that the tonsil does not fall into the throat. This avoids the use of a grasping instrument for the tonsil.

2. The use of a combined crushing blade outside the tonsil, together with a cutting blade close to the former but between that and the tonsil. The crushing blade acts as a hemostat and the cutting blade cuts beyond the crushed vessels, so that there is scarcely any bleeding. The La Force instrument is the main example of this type. The objection to

the method is that the crushing blades are rather thick, so that the resulting picture shows a little more traumatized tissues than in the other guillotine methods. Then the danger of late hemorrhage seems to be increased through the greater sloughing and thus greater exposure of the cut blood vessels. However, many use it exclusively.

3. This type consists of a dull Sluder tonsillotome which grasps the tonsil completely, together with a snare that is applied between the blade and the tonsillar fossa. In other words, the guillotine acts as a grasping instrument and the snare cuts through the mucous membrane edges of the tonsil and the loose areolar tissue just outside the capsule of the tonsil. The Braun snareto me is of this type. The usual Sluder procedure or the Beck modification can be followed, care being taken to apply the blade directly behind the anterior pillar. After ramming the blade through the fenestrum, the shaft of the instrument is rotated slightly backward, showing a dimpling of the tissues just in front of the anterior pillar. This is an indication that the entire tonsil has been grasped (Braun). Now the wheel of the snare is turned until the loop reaches the anterior pillar, and just as the loop is passing this the guillotine blade is slightly loosened so that the loop passes by the anterior pillar without bruising it (Braun). The snare automatically becomes detached from the guillotine as it tightens, so that the latter can be removed and the snare tightened as slowly as wished. It is usually best to tighten it until there is a sudden slight lessening of the resistance, showing that the wire has passed through most of the tissues and is now crushing the pedicular blood vessels. Leaving this in place, the other tonsil is now attacked in similar fashion with another snare.

Less trauma is produced by the two snare modifications of the guillotine operation of Sluder than with the latter. There is no injury or button-holing of the anterior pillars or of the aponeuroses of the superior constrictor muscles, and there is less hemorrhage. The ability to attack the second tonsil with a bloodless field is also a great advantage.

There are a few failures with the various guillotine operations where it is necessary to fall back on the dissection methods. Thin, flabby tonsils are especially difficult to grasp with the guillotine.

During tonsillectomy the tonsils should be wiped or the suction tube applied frequently, especially before, during, and after the application of the snare, guillotine or other squeezing procedures. The suction tip should also be pressed occasionally against the adenoids in the nasopharynx. Observation of this precaution should minimize the danger of septic pneumonia and pulmonary abscesses. During general anesthesia great care must be observed in keeping the respiration unimpeded, especially in children. The latter are frequently subnormally developed and the respiratory centers may easily succumb if cyanosis is long continued. Rubber gloves should be worn by the operator; they do not interfere materially with the sense of touch and prevent adding further infective bacteria.

After removal of the tonsil, the tonsillar fossa is carefully inspected for remnants of lymphoid tissue. The most important area is the supratonsillar fossa. Remnants left there may subject the patient

to attacks not only of tonsillitis, peritonsillitis and peritonsillar abscesses, but may also be a source of infection elsewhere. The lymphoid tissue in the infratonsillar and lingual regions must also be carefully removed. Failure to remove the infratonsillar nodes may result in the refilling of the tonsillar fossæ with lymphoid tissue.

Control of Tonsillar Hemorrhage During Operation.—In sponging, the sponge should be placed gently in the tonsillar fossa, without any rubbing or rough movements over the pillars and adjoining tissues, then pressure applied for a few moments. The electric suction apparatus is very satisfactory for clearing the field of operation and keeping the oropharynx free from blood, saliva, and secretions, and reduces sponging to a minimum. Two sponges can be kept in the tonsillar fossæ on sponge holders so that the shanks of the instruments cross each other, or by inserting the sponges in the fossæ and then opening the blades of a sponge holder so that the blades impinge against the sponges, as strong pressure as desirable can be maintained with the one instrument (Braun). On removal of the sponges the pillars should be retracted and the fossæ inspected first for any remnants of tonsillar tissues and then for hemorrhage. The former should be clipped off with a good biting forceps, great care being taken not to remove or tear any part of the pillars or aponeurosis of the superior muscle. The hemorrhage is controlled by clamping the bleeding spots with hemostatic forceps, straight or curved at the end (Sawtell) leaving them in place for a few moments and then removing them without twisting. Twisting off increases the amount of sloughing and the area of post-operative cellulitis. If the hemorrhage is general oozing of the capillaries and does not cease with pressure or clamping, thromboplastin is often very effectual. Adrenalin can be applied on a sponge until the hemorrhage ceases, followed by 12 per cent. nitrate of silver solution. The former temporarily contracts the blood vessels and the latter contracts all the tissues, ensuring a more permanent clotting of the blood vessel openings. Subcutaneous injections of horse serum, hemostatic serum, or blood transfusions can be tried where the clotting of the blood seems to be at fault. It is rarely necessary to clamp or suture the pillars together.

The Adenoid Operation.—Under general anesthesia it is important to use suction of the adenoid region before removing the adenoids, exerting some pressure with the suction tip so as to squeeze out any excess necrotic material from the crypts. Then palpation should be used to find out the amount, character, and situation of the growths. The La Force adenotome is the most satisfactory instrument in most instances. It usually removes the excess tissue with one or two attempts,—the tissue is brought away entire in a box together with all its infective material,—the blade cuts upward so that if it does not entirely cut through the tissue grasped, the drawing away of the instrument pulls toward a surface already denuded, so that there is no possibility of stripping the mucosa beyond the cut area.

Palpation of the nasopharynx after the first cutting will reveal whether any tissue remains to be removed; if so, the instrument can be reinserted

and pressed toward the spot remaining to be guillotined, another cut being made. This can be repeated as often as necessary. Small collections of adenoid tissue situated in Rosenmüller's fossa, not always reached by the adenotome can be scraped away with the finger covered with a layer of gauze over the rubber glove or, where this is impossible, with a small adenoid curette. Rarely, the adenoid growth may be strongly fibrous and globular in shape, so that it can not enter the box of the La Force adenotome. In such cases there can be a preliminary loosening or cutting of the tissues with a curette, or adenoid grasping forceps, completing the operation with the La Force adenotome.

Removal of the mucosa over the posterior surface of the soft palate is an accident which is liable to produce adhesion with the posterior pharyngeal wall, resulting in mouth breathing, and is exceedingly difficult to overcome with operative procedures. With care it should never occur.

As soon as the adenoid tissue has been thoroughly removed, a small gauze sponge on forceps curved at the end, such as a Sawtell hemostatic forceps, is passed into the nasopharynx and pressure is exerted upward and backward toward the denuded area for a few moments or until the hemorrhage is somewhat controlled. Suction in the oropharynx meanwhile keeps the air way clear. The sponge is now removed from the nasopharynx, the soft palate is drawn forward with a Davis pillar retractor, and the nasopharynx is inspected. If there is still some bleeding, the denuded areas are grasped with Sawtell forceps, which are shifted to different spots until the hemorrhage ceases. Sometimes the bleeding points can be seen and visibly clamped. The forceps are then withdrawn. During this entire procedure suction is used in the oropharynx to keep the field clear. Thromboplastin or some similar preparation can be applied with pressure when the oozing of blood is obstinate, or adrenalin followed by 12 per cent. nitrate of silver solution.

After-Treatment.—There is considerable pain and discomfort after the operation. An ice-bag applied to the neck for awhile relieves this somewhat. If there is very much distress and tendency to hysteria, an analgesic dose of morphine in an adult or codeine phosphate in a child can be given hypodermatically. The dose should not be sufficient to cause sleep, as quite a hemorrhage can pass into the stomach during sleep without attracting attention until it is vomited, and it is important to know the existence of a hemorrhage as soon as possible. For infants and children there should be rest in bed from four days to a week, depending on the condition. For older individuals three days of rest partly in bed materially assists convalescence and the avoidance of complications. A mouth wash or spray of a saturated solution of boric acid every three hours should be used for infants and young children. A mild antiseptic saline solution spray every three hours for the nose and throat for older children and adults keeps the nasopharynx and tonsillar regions fairly clean. There is not much desire for food during the first three days. Cold fluids can be taken first. Hot foods, acid or highly spiced foods, should be avoided for a few days. Constipation must be avoided by appropriate measures.

Other complications. Abscess of the lungs occurs rarely, and almost never after tonsillectomy under local anesthesia. It is probably an inspiration infection occurring during the deep anesthesia, permitting the suction of infectious materials squeezed out of the tonsils or adenoids during the operative procedures. More frequent and continuous use of suction during the operation should reduce the occurrence of this rare accident. Deep cellulitis of the neck may occur but can be minimized by careful avoidance of needless trauma. Metastatic inflammations in other parts of the body may be reduced by the selection of operative procedures causing the least amount of trauma and the avoidance of introducing new infections by the use of gloves and attention to aseptic precautions. Acute otitis in children can usually be prevented by keeping the nasopharynx clean and by the careful supervision of every hygienic detail during the first ten days of convalescence.

CLINICAL AND LABORATORY TESTS IN HYPERTHYROIDISM.

By HENRY R. HARROWER, M.D., F.R.S.M. (Lond.).

GLENDALE, CAL.

THE diagnosis of early hyperthyroidism is difficult if not impossible without recourse to the laboratory. It is easy enough to "spot" the typical cases with the four pathognomonic symptoms; but if the diagnosis is not made in the incipient stage, treatment is not by any means satisfactory. Hence every effort should be made to differentiate hyperthyroidism as early as possible, and for this reason the clinical and laboratory tests deserve to be better known and more often used.*

One of the most constant results of hyperthyroidism is a condition of sympathicotonus, in which the nerve endings of the sympathetic and the vasomotor systems are markedly sensitized to the influence of adrenin; so much so, that slight doses of this principle give a more rapid and decided reaction than is seen in the normal individual. Several tests have been originated which involve this effect, while others, equally or more efficient, are outlined here.

Loewi's Mydriasis Test.—Loewi discovered this test while experimenting with artificial diabetes in animals. He found that the instillation of a couple of drops of 1:1000 adrenalin chloride into the conjunctival sac causes the pupil to dilate within a half an hour, and that this condition remains from 10 to 18 hours after arriving at the maximum divergence, which occurs within an hour after the adrenalin is applied. He reasoned from this that here was a possibility for forming a test to determine sympathetic irritability. The adrenalin stimulated the sympathetic, in turn controlling the dilator fibers of the pupil. Hence, the facts when followed in order argue for the application of this test in latent hyperthyroidism. The thyroid and adrenals are synergistic and both stimulate the sympathetic; therefore, in hyperthyroidism the sympathetic would be irritated and an abnormally early response would follow the entrance of adrenalin into the al-

ready irritable sympathetic system. This does occur and has become widely known. The test is not absolute, but as a routine is of some advantage in filling out a puzzling clinical picture. In Loewi's test it is well to remember that in addition to the mydriasis there is a diminution or total absence of convergence miosis, but the light reflex remains undisturbed.

Goetsch's Test.—Another more popular adrenal test is that of Goetsch, of Brooklyn, a test also based on the excessively irritated state of the sympathetic in hyperthyroidism. Here the adrenalin is injected hypodermically. Eight minims of the 1:1000 solution are diluted with an equal amount of sterile water and injected into the arm. Immediately the area around the point of injection blanches and at the margin of this is a red areola gradually shading off into the normal skin color. In about half an hour the center of the area becomes lilac or lavender in color, and in from one and a half to two hours the red areola becomes of a lavender color, while the similar color at the center disappears. The lavender areola is the characteristic part of the test and lingers for about four hours after the primary injection. The local reaction may be accompanied by augmented hyperthyroid symptoms, such as tachycardia, exaggerated tremor, and anxiety.

Goetsch's test is particularly valuable in the group of cases in which the excessive functioning of the thyroid is responsible for psychoneuroses, psychasthenia, and neurasthenia, without any appreciable ocular, vasomotor, or cardiac symptoms. It is also especially helpful in establishing a diagnosis in latent cases, and has been recommended highly in the differentiation of incipient tuberculosis from early thyroid hypersecretion, as the response is negative in tuberculosis that is uncomplicated by hyperthyroidism. Goetsch believes that a positive reaction in a tuberculous case is accurate proof that hyperthyroidism is present. This procedure has been thoroughly tested at the Trudeau Sanatorium and has been shown to be of value in determining borderline cases with thyrotuberculous symptoms.

Thyroid Function Test.—My own gland feeding test has been used quite extensively in determining the prehyperthyroid state and also to check up clinically on the capacity of the thyroid gland to respond to endocrine stimuli in a given case. A detailed explanation of this test is given elsewhere. It may be well to cover its most salient points here and let the reader's own desires and interests carry him further into the literature. The test is based on the fact that thyroid influence makes its early manifestations by way of the heart, i.e. an increased pulse rate. If the thyroid is irritable and about to start out on a rampant hypersecretory campaign, the pulse will show an early rise and will continue to be rapid for two or more days following the test. A normal thyroid will be but mildly surprised and react accordingly—a slight, fleeting increased rate. The hyposecreting gland pays but little attention to the nudge given it by the ingested glandular substance, and little or no change is observed.

The recommended application of the test consists in giving four daily doses of thyroid extract for three days. The first day $\frac{1}{2}$ grain is given, the second day 1 grain, and the third day 2 grains at

*Metabolimetry is the subject of another paper to be published later.

8, 10, 12, and 2 o'clock. The pulse is taken five times at regular intervals (9, 12, 3, 6, and 9 o'clock) for one day preceding the test, during the three days of the test, and for two days following the discontinuing of the capsules.

This thyroid function test obviously is not a measure intended to be used in frank hyperthyroidism, for the pulse rate in these cases already is high and often irregular. The test was developed by me in the study of latent dysthyroidism, especially those cases presumed to be complicated by a thyroid functional *apathy*. While it is true that latent thyroid *sensitiveness* also is discovered by this measure, it cannot be used when conditions have reached a stage of cardiac irritability and tachycardia. In early cases, however, it is useful and the chart will show clear-cut evidence of the difference in the reaction of a case of thyroid *apathy* as compared with one of thyroid sensitiveness.

A critique of this test is made by Bram, of Philadelphia, and his statement is willingly published here: "The administration of thyroid extract to a patient already suffering with thyroid toxemia nearly always aggravates the symptoms. It is for this reason that it has been administered in specified dosage at stated intervals during three or four days or longer, in order to observe whether existing symptoms are aggravated, or vague symptoms rendered clearer. This test is mentioned merely to be condemned, for not only is its reliability as an accurate and useful supplement in diagnosis called into question, but a hyperthyroidism formerly more or less latent may be whipped up to become very active and malignant in its course." This merely emphasizes, in perhaps a somewhat exaggerated way, what I have repeatedly stated, namely, that the thyroid function test is not a test for frank hyperthyroidism.

Glucose Tolerance Test.—Since the work of Tachau in 1911, much has been done in the study of alimentary hyperglycemia in hyperthyroidism. The older methods of blood analysis were slow and complicated, and hence such investigation could not be carried out extensively until the simpler methods of blood sugar determination were brought into practical use by Lewis and Benedict, Meyers and Bailey, and other technicians.

As in the estimation of the basal metabolism, the discussion of which must be left for another paper, it is necessary to eliminate all sources of error by fasting and resting, so in the blood analysis for glucose it is necessary that the patient fast before the blood is taken. The patient is then given 100 grams of glucose by mouth. One hour following its ingestion a second blood specimen is taken, and in another hour a third sample is drawn. It is well to examine the urine before the test and at the time of withdrawal of each blood sample, although the glycosuria that may be present is not of such diagnostic importance as one might at first think, as the urinary sugar would only involve what is termed "the renal glucose threshold" rather than the thyroid function. A normal individual who has ingested 100 grams of glucose does not show an increased blood sugar content that lasts an hour. There is, however, an immediate increase of blood sugar, but this soon subsides before the hour is up. A few exceptions occur to all rules but the hour

limit is a safe one to set for normal people. Probably half an hour is usually sufficient to lower the crest of the sugar wave. The technique of the method is found in the papers of Wilson, Smith and Janney.

In hyperthyroid cases the sugar wave, plotted from the several findings, reaches its crest at the end of the first hour—falling to normal by the end of the second hour in the great majority of cases. So constant is this finding in hyperthyroidism that it corresponds favorably in diagnostic import with the basal metabolism test. It makes no difference to the diagnostician whether the findings of the basal metabolism test or the blood sugar results are due to a direct action of the thyroid or indirectly are brought about by the influence of that gland—the fact remains that these two tests are constantly positive in hyperthyroidism and are highly necessary to the physician in accurately determining the prognosis and treatment of his suspected thyroid cases.

McCaskey's final decisions regarding the value of the study of the alimentary hyperglycemia are as follows:

1. That alimentary hyperglycemia following 100 grams of glucose is present in probably every case of thyrotoxicosis.

2. That it is rarely, if ever, present at the end of the first hour in normal persons, although it may have occurred at the end of about thirty minutes.

3. Its presence, therefore, in one hour and especially in two hours always indicates abnormal carbohydrate metabolism unless the gastrointestinal function is delayed.

4. It occurs in latent, and of course in manifest diabetes, in alcoholism, malignant disease, arthritis, and very probably in a considerable number of infections—acute, subacute, or chronic—in the same category with arthritis.

5. Before attaching a positive diagnostic value to alimentary hyperglycemia in suspected hyperthyroidism, these conditions and possibly others of which we are now learning must be excluded.

6. While its positive value can only be considered corroborative, its negative value in excluding hyperthyroidism is very great and probably exceeds 90 per cent.

7. In hyperthyroidism there is no constant direct ratio between its intensity and the height of the alimentary hyperglycemia, although in general the blood sugar values are high in severe cases.

8. Too much importance should not be attached to alimentary blood sugar values below 140 mg. of sugar in 100 c.c. blood, although sharp lines of demarcation cannot yet be drawn.

The Quinine Test.—Bram of Philadelphia has recently reported a procedure which consists in the progressive administration of quinine by mouth: "The patient is given a dozen capsules, each containing ten grains of the neutral hydrobromide of quinine, with instructions to take one capsule four times a day, to be washed down by an ample quantity of lukewarm water, an hour or two after meals and at bedtime. By the time thirty, forty, or fifty grains have been taken by persons whose thyroid function is not excessive, there develops a sense of fullness in the head, impaired hearing with tinnitus, often dizziness and headache, and occasionally a

feeling of slight gastric and bladder discomfort. Persons possessing a degree of susceptibility or idiosyncrasy will experience these symptoms after the first or second capsule, while those to a degree tolerant may not complain until sixty to one hundred grains have been taken. In the presence of a hyperactive thyroid, no symptoms develop from the daily administration of quinine hydrobromide even if given during a period of weeks or months; on the contrary, improvement in the Basedowian syndrome is frequently observed." Subjects of thyrotoxicemia are exceptionally tolerant to quinine administration during the course of the disease, and for a long time, usually years after the cessation of the thyrotoxic process. In fact, this toleration to the drug in moderately large doses practically amounts to an immunity.

According to Bram, "the quinine test seems valuable and quite reliable because of its simplicity in application, its harmlessness, and the fact that it does not require an especially trained individual to make the observation. Though there may be a 5 per cent. to 10 per cent. error in its use, it is especially commendable since its interpretation does not depend upon an aggravation of the symptoms of hyperthyroidism, but there is rather an improvement of the Basedowian syndrome in many instances.

Aberhalden's Ferment Test should be mentioned, though I do not believe it to be practicable in the hands of the clinician. Rosenbloom of Pittsburgh gives a recent and very comprehensive consideration of this subject and the somewhat complicated technique of the method. Lampe of Halle and others have thought that the serum of hyperthyroid individuals contains a specific antibody to thyroid tissue and they suggest that this can be determined by following the somewhat complex system of determination originated by Aberhalden.

The Pituitary Test, originated by Boudouin and Porak of Paris, is also used to determine the presence of excess thyroid principle in the blood stream. One milliliter of the extract from the posterior lobe of the pituitary gland (Liquor Hypophysis, U. S. P.) when injected into the patient causes the pulse to become slower within two minutes of the injection. In thyroid toxemia this effect disappears in about eight minutes. In normal individuals the injection of a similar amount of liquor hypophysis causes an acceleration of the pulse, which shortly becomes stationary in five to seven minutes and usually returns to the normal within fifteen minutes.

Marañón's Skin Reaction.—A certain dermatographic sign, believed to be quite commonly present in hyperthyroidism, has been described by Marañón of Madrid. Since he noted it present in 92 out of 100 cases, irrespective of their clinical type, it seems worthy of mention here: "By slightly rubbing or pressing with the fingers the integument of the throat an intense vasomotor reaction may be provoked. It is not confined to the area rubbed but may extend to the anterior wall of the thorax. In goitrous subjects the distribution is markedly influenced by the area of the goiter, whether unilateral or bilateral. The red area may be continuous or dissociated, and in certain cases an urticarial component is evident, the area showing slight elevation. The mere fact that the practi-

tioner is about to compress or stroke the skin may cause the phenomenon without actual contact. A blush may appear independently on the thorax or other distant point. A proportional or quantitative behavior has not been seen, and the vasomotor irritability is quite independent of the degree of hyperthyroidism in a given case. The author claims a certain priority in calling attention to this symptom, although Chvostek has called attention to the unmotivated blushing of the hyperthyroid subject. The author believes that excess of thyroid or altered thyroid secretion has sensitized the vasomotor apparatus and he would place the phenomenon under sympatheticotonic manifestations. It is seen predominantly in women, in the young, and at the menopause."

A French cardiologist, by name Lian, believes that tenderness in the region of the thyroid is an early sign of a tendency toward hyperthyroidism. The cardiac symptoms in the minor forms of hyperthyroidism may be mistaken for a cardiac neurosis. The tachycardia may be moderate and occur only when standing or working or under emotional stress. Certainty is attained in these questionable cases by the pain expressed when the thyroid region is palpated or explored with the point of a pin.

Berkeley and Koopman report a new test for checking up on a clinical diagnosis of tentative hyperthyroidism. From their statements it would appear that this test bids fair to be as reliable as the blood Wassermann for lues, having been used by them in hundreds of cases with controls to offset error. The reaction is thought to be due to a specific thyroid substance which combines with the antibody in the patient's blood.

REESTABLISHMENT INSURANCE.

ORGANIZATION FOR THE PURPOSE OF ADDING MATERIALLY TO LENGTH OF DAYS AND ENHANCING PRODUCTIVITY.

BY J. MADISON TAYLOR, A.B., M.D.

PHILADELPHIA, PA.

PROFESSOR OF PHYSICAL THERAPEUTICS AND DIETETICS, MEDICAL DEPARTMENT, TEMPLE UNIVERSITY.

The most useful, practical, and paying field of medicine is only beginning to be developed. That is systematizing the resources and measures for raising and prolonging the coefficient of working powers in those of middle life, while one is at the zenith of one's trained capabilities.

The profession has attained ample knowledge and expertness in maintaining survival and productive values, but as to this the public is slowly awakening or appreciating. Having aimed at this objective for a life time, and like others suffered discouragement from indifference, it has become my conviction that the only way to seize and hold attention to this self-sacrificing enterprise is to reduce to a strictly business basis the problem of preventing decrepitudes. Not until a captain or private of industry can be shown how he can earn or save more money, is it feasible to get and hold his attention to a health conserving proposition.

Like all novel ideas, or unfamiliar applications of established principles, this one of adding not only to length of days but to working powers, will take some time to make itself a part of customary business procedure. Reasons for acceptance may be complete but realization comes slowly, conviction more slowly, and action most slowly. Only after long years of demonstration, through vast accumu-

lations of evidence, is it possible for a novel business method to become established in the folkways of society.

It is an accepted fact of the mind workings of the group, of social psychology, that currents of human conduct depend on leadership. Such leadership is the product of business foresight, rather than that of urgent or conspicuous economic needs. The want may exist, the urge may be strong, but the demand will not become expressed until the way is pointed out, clearly, repeatedly, and through a mass of experiences and demonstrations. The first deciding factor is the offer of an attractive safe business proposition.

Life insurance as an enterprise developed slowly, but it is now esteemed as a human necessity, just like government, banking, or public utilities, or transportation, or sanitation, and the like. From the enterprise of insurance on lives, there evolved other forms, safeguarding against loss through accidents, the supplying of annuities, etc. An equally important demand is now becoming felt for the insurance of personal capabilities for sustaining productivity, for postponing decrepitudes, for fortifying the individual against the evil days of incapacity, of dependency on the earnings of others. Leadership is here plainly needed and is to be supplied by insurance companies, whether through the amplification of those organizations now established, or for the organization of new ones especially designed for the reestablishment of waning powers.

The objectives of life insurance at present seem confined chiefly to supplying funds to the survivors, financial aids, annuities, borrowing values, credits, and the like during the life of the insured person or "risk."

Other objectives should be, and can readily be, supplied of equal or greater value. The chief of these objectives, the one here being presented, includes three new economic advantages, (a) practical and scientific measures devised to prolong life, and (b) the prevention of premature senility, decrepitude, disability, hence dependency, (c) thus adding to the earnings of the companies.

The question before us is: can this be done, and if so how can it be made to become a desirable business proposition, and how to render it worth the while of the insurance companies?

This problem was explained, and a plan for its solution offered by me, in a paper in the *New York Medical Times* May, 1920, entitled: "Conservation for Mature Adults as a Fine Art in Medical Specialization, with Special Reference to Amplifying the Scope of Life Insurance." These facts and propositions were submitted to the medical directors of all the larger life companies as many as four times and forms. No notice, practically, was taken of my communications. Why?

Competent business men, and also insurance experts confidently assured me that the reason for this indifference to my sendings was the fact that no strictly or definitely business proposition was offered, no obvious method of reducing the proposition to a dollars and cents basis, for the life companies to work upon. It would seem that as yet money making is the chief, perhaps the only, consideration and not the essential welfare of the in-

sured person. This omission it is my purpose now to offer means for supplying.

I will sketch out the present proposition and then proceed to outline succinctly the scientific basis for the economic recommendations:

One of two forms of policy may be offered, either (1) to supplement the present forms and conditions by adding a clause to the effect that, in addition to any existing contract the insured person shall further covenant to accept and abide by the advice of qualified experts in human conservation designed to raise the coefficient of survival and productive values, to prevent premature senility, decrepitude, or disability, hence dependency, upon a basis to be set forth, or (2) to organize a separate company to issue a particularized form of policy, which contract can be sold at a much less price than the older forms because the risks will thus be materially reduced, and to a point of far less premium price than is possible with the forms of contract now in use. This policy may be described as "Reestablishment insurance" or some other suitable wording.

Now as to the improved conditions readily made available: The periods of greatest mortality are in infancy and maturity; the causes of increased mortality at both periods almost solely arise in ignorance or carelessness.

We will deal here only with the perils of maturity. Advances in medical knowledge have made it entirely possible to reduce mortality and decrepitude by the simple device of employing and following expert supervision of conduct, improvements in methods of living, or working conditions, in short, conservative personal hygiene. This enterprise by no means places any demands upon individuals to change in any objectionable way their present conditions of living or of working, except in certain rational particulars and in accord with even fuller satisfaction than before.

As to details, particulars, methods, etc., these are set forth in a book by me, now in press, entitled "The Man Who Would Be Young at Fifty."

Almost limitless resources are supplied by reconstructive hygiene, or a better term reestablishment, or conservative personal hygiene. This is the taking of an individual at any age, in any condition of life, and revising the living conditions on an economic scale, thus bringing out latent, unused, or unelaborated forces or potentialities through the use of specified improvements, here and there, in personal conduct. Thus it becomes perfectly feasible not only to raise the energy status, to overcome primary developmental defects, but also materially to remedy many effects of previous depression, deterioration, or disease or injury.

It is obviously worth while to induce an insured person to understand the significance of these facts—they are fully established matters of knowledge common to the medical profession—also for clients or risks to be induced by monetary considerations to assume a contract obligating them to learn precisely what their survival and productive status at that time is. By conforming to certain recommendations it will become practicable that their lives shall be prolonged in a manner, and to a degree, consistent with their hereditary, constitutional, or acquired endowments.

A necessary condition would be that the policy holder conscientiously shall abide by the findings of experts, in order to enjoy the special privileges provided by a contract which specifies these privileges and obligations.

Thus a purchaser of insurance gets what he pays for, a greatly enhanced productivity and expectation of life. Also he pays less by reason of accepting these conditions. The company offering the contract simply makes specific conditions through special experts, the chief of which are recommendations as to what to do and what not to do. These experts act in the interest of the companies quite as much or more than in the interest of the insured.

Such consultants would of course vary as to their knowledge in different particulars. The paramount desideratum would be to supply capabilities for raising the coefficient of efficiency in the organism as a whole. This would include skill in dealing with disorders of personality as well as of structure and function.

Proposition for Reestablishment Insurance.—The proposition includes the selection by the companies of a group of qualified experts in life prolongation and of constitutional reestablishment. These expert consultants may be as many as shall be determined, or as can be secured, and in locations and in positions accessible to policy holders.

The mode of procedure might be somewhat as follows, details to be worked out: Let there be organized a group of qualified experts in life and invigoration conservation. From these men the family medical adviser of the insured shall be privileged to select one or more, or to change as desired. The consultant acts upon his own accountability, in accord with his own capability.

The consultant selected shall make, or have made, all necessary examinations, also an appraisal of the conditions or status of the "risk"; or he may indicate what special laboratory or other examinations shall be made, convenient to the risk, or through the collaboration of the family adviser. He shall then assemble the findings, formulate a series of recommendations in accord with the needs as found, and then send copies in triplicate: (1) to the insured individual, (2) to the family physician for his comment and consideration and to carry out details, and (3) to the medical director of the company. Thus there is a four-cornered copartnership of interested individuals or parties, the insured person being the fourth.

The insured persons should submit themselves for conference and inspection to the expert consultant once in so often, consonant with the needs of the conditions found, or as may be agreed.

In the instance of an individual of excellent physical status and habits and capabilities, willing to cooperate in spirit as well as letter, the supervision need be only occasional. The conditions for success are, however, consistency and faithfulness in cooperation, and a recognition of the special obligations.

Remarks.—That period of life—full maturity—when one's powers of mind, of body, and of proficiency are at their highest, is also the period when the most serious perils, or organic deteriorations, assail. The gravest carelessness or ignorance is then too often exhibited as to personal welfare.

At full maturity the earning powers are at their zenith through multiplied and elaborated experiences, habitudes, and special trainings.

These earning proficiencies and facilities are called "automatics" whereby one is capable of doing many times more work than before, and with the least expenditure of effort. This zenith of productivity remains for only a few years at best. Capabilities can be indefinitely prolonged by wise economies of energy, of structure, and of functional integrity.

Obviously it is desirable that every effort shall be made to conserve these productive automatics, as well as elaborated powers, for service and enjoyment. At least it is well worth while to postpone decrepitude, a state of dependency on others.

As a people we are too prone to let well enough alone. We need rational or financial inducements to bring and keep our bodily and mental fitness up to par. We have, however, been sharply impressed of late with the economic value of sustaining physical and mental soundness. Emphatic evidences are adduced by the confusions and blundering prodigalities wrought by the world war.

We have been subjected to extraordinary and severe stresses upon body and mind, many of which become destructive, but are capable of remedy by judicious regulation of conduct. In short, the average citizen needs expert explanation, counsel, and consistent encouragement to pursue right courses of action. The tendency of the individual is to neglect seeking such counsel unless urged upon a pecuniary basis. This endeavor the life insurance companies can, and should, encourage to the advantage of both the company and the individual.

It is a matter of common knowledge that while there are available, in every civilized community, many physicians fully competent to reach admirable diagnoses and to treat conditions of disorder, disability, or acute or chronic illness, there are relatively few who also interest themselves in the more practical aspects or systematic methods of raising the coefficient of efficiency in accord with personal equipment and design.

Obviously it is desirable that those who are qualified to contribute to raising the coefficient of robusticity, productivity, and survival, should be encouraged to do so and be given adequate opportunities for specializing and in rendering service. It is equally obvious that such expert counsellors could be enabled to contribute their powers to human welfare, and that the best means of doing so is through economic and beneficent organizations on a business basis.

1504 PINE STREET

The Emotional Reaction.—Waller of London described before the Société de Biologie de Paris what appears to be a variation of the psychogalvanic reflex (although he does not make use of that expression). If the hand and later the forearm of certain subjects are intercalated in a Wheatstone bridge, the passage through the sensorium even of a minimum emotion will cause a sudden diminution of the electric resistance measured from the palm to the back of the hand. We may make three types in regard to resistance: normal, supernormal, and subnormal. In the supernormal the test is positive even in the forearm, while in the subnormal the reaction is absent even in the hand.—*La Presse Médicale*.

TRIPLE CALCIUM PHOSPHATE AS A STIMULANT FOR BONE REPRODUCTION (HEALING) IN FRACTURES.

By R. J. BEHAN, M.D. (Pittsburgh and Berlin), F.A.C.S.,

PITTSBURGH, PA.

SURGEON TO ST. JOSEPH'S HOSPITAL, AND TO THE PITTSBURGH HOSPITAL FOR TUBERCULOSIS (LEECH FARM).

In the winter and spring of 1912 and 1913 Dr. Schultze and myself were engaged in a series of experiments to determine the manner in which embolism occurs from fractures, especially when they take place in old tuberculous areas and ankyloses, when, during an attempt at reduction the bone is fractured. In one year at Professor Lorenz's Clinic in Vienna, two patients died during the forcible correction and reduction of an ankylosed joint. It is nothing unusual for a fracture, especially in the old, to lead to embolism of the lung and death.

While engaged in the work of determining the cause of the frequency of these emboli, we became interested in the factors which are active in causing bone to unite after a fracture. The two essentials necessary for the union of a fractured bone are first, cells, which are active in forming the structure of new bone; and second, calcium phosphate, which is deposited in such bone and renders it hard. The cells, which are concerned in the formation of new bone are practically always present at the site of fracture. They are supposed by some to be the connective-tissue cells, which metamorphose in one direction into fibroblasts, and in the other direction to cartilage, and then to bone forming cells. At the site of the fracture there are two types of cells, the fibroblasts and lacunar cells, which are also present in bone. The lacunar cells consist of two varieties, the osteoblasts, which form the bone; and the osteoclasts, which are the phagocytes, the destructive elements in bone, i.e., the cells, which form the lacunar spaces. These osteoclasts are possibly a further development of the osteoblasts; some claim they are marrow cells.

For the formation of bone it is necessary that a matrix be present. This is in the form of connective tissue joining the ends of the bone. This connective tissue deposit is likely the result of the activity of the fibroblasts. Later from the osteoblasts, which are drawn out from the haversian system and the lacunar cavities, the deposit of calcium begins to take place. Cavity formation corresponding to lacunar spaces is formed. These cavity formations finally become larger and are broken down by the osteoclasts, until typical bone develops between the fragments, and union takes place. The question now arises, how and in what manner are these regenerative factors stimulated into activity? What is the influence that causes fibroblasts to increase in number, and draws out the osteoblasts from the bone spaces? In the work which Dr. Schultze and myself did, and recorded in the *Münchener medizinische Wochenschrift* in Dec., 1913, we found a negative pressure 0.8 mm. water in the medullary cavity of the tibia of the dog.

This negative pressure in the cavity of bone would have a tendency to keep the cells intact and to draw the blood from the cortex into the large medullary spaces. If suddenly, through a fracture, the con-

tinuity of the bone is interrupted, this pressure would be changed, so that instead of being negative, it would be positive. The tendency would be for the bone to bleed on its ruptured surface, so that cells and other materials would be thrown out of, instead of being drawn into, the medullary cavity, and would be emptied from the surface of the bone, or at least from the broken ends of the fragments. In this way bone cells would likely be included in the blood clot.

However, in an experiment which was made by us, we were unable to develop any bone from a centrifuged specimen of 10 c.c. of blood, which had been collected at the site of a fracture.

Other elements may be active in stimulating bone regeneration, such as the presence of a chemical substance at the site of the fracture, this chemical substance acting as a stimulus. It is known that all cells have an exciter, which stimulates them to vital activity and reproduction. In animal cells, it is generally some toxic body which has been cast off.

Ross, in his work on reproduction in cancer, found that a substance which he called cadaverine, when supplied to cells, will cause an increased reproduction. He also found that this substance resembled theobromine, which has a similar action. In the study of Ross's work, we were impressed with the fact that there is in every tissue a substance which will stimulate cellular reproduction of the cells of that tissue. We were also impressed with the fact that where there is inflammation of the bone there is a great deposit of calcium salt in the inflamed area, and that this calcium salt seems to be taken away from the surrounding bone structures. This is particularly in tuberculosis of bones in the neighborhood of joints. We were also impressed with the fact that the more extensive a fracture, the greater is the amount of callous formation.

In inflammation of the bone, the bone is destroyed and calcium is liberated. This liberated calcium evidently must act as a stimulating factor for increased bone production. Where there is considerable destruction of bone tissue, the same thing takes place. The fragments of bone become dissolved and the calcium is freed, thus permitting it to stimulate to an abnormal degree in bone cells, which are present in the area of its deposit. With these facts in view, it was thought that calcium or phosphorus or the combination of both in the form of calcium phosphate might be the stimulating agent for bone growth and it was decided to use calcium phosphate and see what effect it would have upon bone reproductive activity. These experiments were performed, and I give them below.

The following experiment, made on Jan. 17, 1913, indicates the effect which calcium phosphate has upon new bone formation. On this date the medullary cavity of the tibia of a dog was opened by a drill hole through the cortex and a considerable quantity of calcium phosphate was introduced into the medullary cavity. The hole was then plugged with an ivory peg. On Feb. 9, twenty-three days later, the dog died. At first it had been slightly ill, but then improved. Recently, it had become very sick. Examination showed that the bone had greatly increased in size. It was as thick again as normal, extremely hard and dense. The growth seemed to be subperiosteal.

The following experiment performed also indicates that there is likely a bone formation when calcium phosphate is used. On Feb. 17, 1913, a trephine opening was made into the tibia and some of the marrow was removed. This, along with calcium phosphate, was inserted into the abdominal muscles on the left side. The opening of the bone was then filled with calcium phosphate, which was also sprinkled in between the muscles.

On examination, March 3, 1913, a small lump was found at the place where the marrow had been implanted in the abdominal muscles. On sectioning, there was no evidence of bone formation. On March 7 the dog was killed. The periosteum was found much thickened. The trephine opening in the bone was already closed by a hard mass. The calcium phosphate showed as a dark chocolate-colored grumous mass, between the muscles and over the bone.

On March 5, 1913, a piece of muscle was inserted between the periosteum and the bone on the tibia of a dog. Calcium phosphate was also inserted between the muscles. When the dog was killed, the limb from which the periosteum was dissected free, and muscle tissue inserted beneath showed a thick layer of fascia separated from the bone with a longitudinal depression corresponding in shape to the free slit of periosteum. Closer inspection showed a thin layer of tissue resembling cartilage.

On Dec. 16, 1912, a piece of periosteum from the tibia was carried through the muscles on the outer side of the same limb. One end of the periosteum was left attached to the bone. On March 6, when the dog was killed, the periosteum, which had been passed through the muscles, could hardly be recognized as such. It, and the adjacent surrounding fibres, formed a thick mass of tissues.

From the above experiments it seems that in no case were we able to definitely form anything resembling bone, except in those cases where calcium was in association with bone itself. In these instances, the calcium seemed to be an active inciting agent for the formation of new bone.

Even after the bone structure has been laid down there may be an absence of calcium salt at the part. This exhibits complete ossification. Calcium salts can be supplied by two methods: first, through the blood, and second, by direct implantation. In supplying calcium through the blood it is well to feed the person upon tissues containing plenty of calcium. At the same time they must have a normal amount of vitamins in order to supply the fundamental principles necessary for the cellular reproduction. These vitamins are contained in vegetable foods and in fresh milk, which has not been sterilized. They may also be found to a certain degree in yeast. However, the chief essential is calcium, and this can be supplied directly by using it in drug form in the different solutions of calcium phosphates, etc., which are now on the market. A direct supply of calcium phosphate is brought about by the surgeon when he inserts bone fragments around the line of a fracture. Every surgeon knows that the insertion of these fragments will stimulate bone growth. He also knows that these inserts do not live; therefore, it is due to the breaking down of the fragments and their absorption that calcium phosphate is freed. We have made use of this fact

and have supplied calcium directly to the bone by injecting it through needles with a syringe, in cases in which a fracture is not uniting rapidly. In cases requiring an open reduction we have smeared the ends of the fragments with calcium phosphate in the form of a paste made of calcium and water, or have rubbed the calcium phosphate directly into the bone tissues. Calcium phosphate in both of these conditions seems to have a great stimulating effect upon the regenerative powers of bone.

These results were confirmed experimentally by Dr. Albee in work done at the U. S. Army General Hospital, No. 3, at Rahway, N. J. (See *Annals of Surgery*, 1920, lxxi., pp. 32-40.)

JENKINS ARCADE.

A CONCEPT OF X-RAY PATHOLOGY.

XI. ESOPHAGOPATHY.

BY A. J. PACINI, M.D.,

WASHINGTON, D. C.

CHIEF OF LABORATORY AND X-RAY SECTION, HOSPITAL DIVISION,
U. S. PUBLIC HEALTH SERVICE.

UNDER ordinary conditions the gastroenteric tract is of varying degrees of radiolucency and even radiopaque; so that it is necessary, for the determination of x-ray pathology, that there be introduced into the canal a radiopaque mixture. The desired qualities of the radiopaque mixture are determined by the part of the tract examined.

It is well to conceive the gastroenteric tract as a continuous muscular tube lined throughout with mucous membrane and at every point dominated by the sympathetic nervous system. There has been much to indicate the importance of the autonomic control of the viscera; but there seem to be relatively few who take any especial cognizance of the effects of the sympathetic control when studying the gastroenteric tract, by its motility, under the fluorescent screen.

It would appear that, anatomically, there are two types of physiological activity present in the vegetative nervous system. The one has been termed sympathetic; and the other parasympathetic or autonomic. The nonvoluntarily influenced organs, smooth muscle structures, heart muscle, and glands derive their innervation from the spinal cord from the first dorsal to the fourth lumbar segment, and in a narrower sense, belong in the sympathetic system. All other structures are controlled through the parasympathetic or autonomic system. Both systems are mutually antagonistic in their muscular effects, but are mutually cooperative in maintaining a physiological balance in the parts by them innervated. The interdependence of the two systems is at once obvious; and any influence that may affect one system may indirectly yet positively affect the second system. That this is so may be inferred from the clinical division of sympathetic and autonomic system disorders into three major groups: (1) Angioneuroses; (2) trophoneuroses; (3) organoneuroses.

Among the organoneuroses there are well established gastrointestinal syndromes. In this group would be included tabetic gastric crises; but equally important to the x-ray pathologist are also the vagotonic manifestations in the gastrointestinal tract including esophageal cardiac spasms, sialorrhea, retarded peristalsis, hypersecretion, and hyperacid-

ity accompanied by pylorospasm. These disorders are not yet completely analyzed, but they are of extreme clinical importance, they being particularly accentuated and their manifestation offering markedly impressive phenomena during the x-ray investigation of the gastrointestinal tracts of those suffering from war neuroses.

X-ray pathology of the gastrointestinal tract is elicited from studies in contour. These studies are directed first to the determination of the absolute contour and secondly to the time study of the rate and manner of food-bolus progress. For purposes of x-ray study the tract may be divided into six sectors: (1) The esophagus; (2) the stomach and the duodenum; (3) the jejunum and ileum; (4) the ileocecal locus; (5) ascending, transverse, and descending colon; (6) the sigmoid flexure and rectal ampulla.

ESOPHAGUS.—For the elicitation of esophageal pathology the patient should preferably stand or sit so that the esophagus is vertical; he should be rotated at an angle of about 45° to procure an oblique view, preferably right anterior oblique position. The exact angle is determined beforehand by fluoroscopic examination, rotating the patient until the greatest space is obtained between the shadow of the vertebral column and that of the heart and aorta. After satisfactory posture, the patient is fed the bismuth mixture recommended by Hirsch.* As the bismuth-acacia descends the esophagus it coats the walls along its path. Each mouthful may be followed along the entire course of the esophagus. Other methods have been suggested by various writers for outlining the esophagus. Bassler used a tube with a distensible rubber bulb at the end which he introduced into the stomach, filled the tube and bag at the tip with water, and pulled the tube up so that the water distended bag blocked the cardiac orifice. After thus sealing the esophagus he introduced a barium suspension through the mouth.

Crimp used a sealed sausage skin, which he had the patient swallow, and then distended it with an opaque suspension. This method often requires co-cainizing the pharynx.

Since the form study of the esophagus is instrumental in arriving at an inference of the type of pathology present, obviously the x-rayist should be familiar with the anatomical normality of that organ. It presents a total length of about twenty-five centimeters; it has an irregular caliber presenting five definite constant constrictions. These are (Carman): (1) At the introitus, (2) at the aortic arch, (3) at the crossing of the left bronchus, (4) at the esophageal hiatus, (5) at the cardiac opening.

Carman divides the swallowing act as observed with the x-ray into two phases, a pharyngeal and an esophageal. At the first phase the food mass accumulates before the esophageal introitus, where it exerts pressure until the sphincter relaxes. In the second phase, the food courses down the esophagus arriving at the cardiac sphincter, where it is momentarily halted, and then enters the stomach. The time required for the passage varies a great deal

*Bismuth subcarbonate, one-half ounce, in mucilage of acacia, one dram. When first mixed the paste is dry and granular; but by continued stirring it becomes smooth and homogeneously viscid.

with the consistency of the suspension. There seems to be little significance attached to the peristaltic waves of the esophagus. They may be present or absent; but they attain no known pathological significance unless exceptionally exaggerated, as in stenosis, or their direction reversed, as in obstruction. Both of these variations are not frequently visualized.

The shadow of the esophagus may retain a normal morphology, the entire tube changing its relatively normal position by reason of the pressure exerted against it owing to the concomitant presence of an aneurysm or of pleural, pulmonary, or mediastinal inflammation, tumors, substernal thyroid, vertebral disease or deformity, or cardiac enlargement. The displacement is quickly recognized as is sometimes the cause; or the morphology may change as the result of an addition as in the case of diverticulum; or the normal diameter at any point or along the entire tube may be increased owing to dilatation, or decreased owing to a stricture or stenosis; or the continuity may present a tear as the result of rupture; or the normal smoothness of the esophageal wall may show local roughening due to ulcer or marked deformity due to cancer. In addition to the morphological changes, one must observe the character and rate of the food passage particularly with reference to the possibility of an arrested progress at any point.

Spasm of the Esophagus.—Spasmodic stricture of the esophagus may be met in hysterical patients and in cases of chorea, epilepsy, and particularly hydrophobia (Osler). There is no complete survey available in the literature that deals with the autonomic reflex morphological changes that affect the esophagus as a result of neuropsychiatric disturbances; but it should be remembered that the sympathetic control of the esophagus is real and may be so perturbed as to induce form changes that simulate organic pathology.

Sometimes the irritant point exciting reflex spasm may be situated along the esophageal tract itself. This is so in those cases where a foreign body lodges in the esophagus and by its mechanical presence and pressure induces a reflex spasm at the point of irritation, or above or below. Spasm may also result when there is present in the esophagus a small abrasion or ulceration. In some cases the size of the ulcerative lesion is apparently out of all proportion to the severity and persistence of the spasm induced. Barclay also subscribes to this opinion and adds further his belief that esophageal ulcer is probably of greater occurrence than is generally taught. The esophageal spasm offers little difficulty in its recognition. Paralysis of the esophagus, a very rare condition and most often due to central disease, may sometimes simulate esophagismus. If the x-ray examination is conducted after an attack of diphtheria, and spasm is elicited, the possibility of a peripheral origin paralysis must be excluded. Belladonna tincture, in ten drop doses, may relieve esophageal spasm.

In esophageal spasm the law of contrary innervation is sometimes beautifully exemplified. The law is a practically derived one and amounts to this: that there are essentially two innervating systems, one dilatatory and the other constricting, involved in the musculature of the entire length of the

alimentary tract. At any given point in the course of the tract the lumen is determined by the algebraical sum of the two phenomena. If a lesion exists at any locus, and that lesion exerts a depressing or stimulating effect on either set of nerves, there is a break in the balance of the forces with the result that either the dilatatory or the constricting action is increased. At the site of the lesion the irritation is initiated. Above the site there may be dilatation, below the site, constriction; or, the reverse may be true, there being constriction above and dilatation below the point affected.

In spasm the point of constriction in the lumen is immediately recognized by the conical tapering of the shadow; and it will be observed that distal to the constricted point, the lumen is greatly narrowed, whereas proximal to the constricted point the lumen is distended with equal greatness.

Cardiospasm.—When the spastic constriction is localized at the entrance of the esophagus into the stomach, the condition is known as cardiospasm. It is typified, in its x-ray pathology, by either a blunt or a regularly conical obstruction at or near the stomach with dilatation of the esophagus above. It is important to note that in cardiospasm the tapering bismuth opacity is everywhere smooth. There seems to be, in some cases, a tendency to extreme dilatation, strongly bearing out the law of contrary innervation. When the spastic constriction is intense, the proximal dilatation is great; and when the spastic constriction is more moderate, the proximal dilatation is less exaggerated.

The x-ray appearance of cardiospasm in no way differs from that of ordinary obstruction at the cardiac orifice excepting that in cardiospasm the initial proximal dilatation is primarily the result of neurorelaxation, while in obstruction from other cause the proximal dilatation is primarily the result of muscular loss of tone. When the condition of obstruction, whether from cardiospasm or other cause, has persisted for some time, the proximal dilatation in both cases is the result of muscular atonicity.

It is unfortunate that constriction resulting from traumatic origin may sometimes give a regular and smooth tapering of the bismuth radiopacity; so that it is not always possible from the x-ray pathology alone definitely to state that the constriction is a spastic one in contradistinction to the anatomical strictures following trauma or new growth.

In cardiospasm the constriction may be dilated with a hydrostatic bag. In some cases the administration of atropine may relieve the spasticity. There were two cases of cardiospasm and four of organic stricture in which the bismuth acacia suspension was medicated with adrenalin hydrochloride.* In the two cases where the cardiospasm was pure, marked peristalsis was not induced in the walls of the dilated esophagus; but in the four cases where the constriction was organic, the adrenalin bismuth mixture initiated markedly violent peristaltic undulations in the expanded esophagus. It may well be that the use of adrenalin may make for x-ray differentiation in the cause of cardiac esophageal constriction.

*Bismuth subcarbonate, half oz.; mucilage of acacia, one dram; solution adrenalin hydrochloride (1:1000), fifteen minims.

Diverticulum.—Zenka's classification of pressure and traction diverticula forms a convenient x-ray classification. Pressure diverticula are most common at the junction of the pharynx and esophagus, and seem to favor the posterior wall. Traction diverticula affect primarily the anterior wall and are generally situated in the region of the bifurcation of the trachea.

Those of the pressure or pulsion type are more numerous. They may vary in size from five to fifteen millimeters. As the bismuth suspension flows along the esophagus some of the opaque mixture may enter the pouch and remain there, while the rest of the fluid flows into the stomach; so that the x-ray pathology of diverticulitis is that of a smooth radiopaque area at the junction of the pharynx and esophagus. Traction diverticula are associated with inflammatory conditions involving the bronchial gland. By extension the inflammatory glands impinge upon the esophagus and incite, at the common focus, sympathetic inflammation. The process may go on to chronicity and there may remain a permanent adhesion between the inflamed glands and the esophagus. As the inflammation assumes greater chronicity, gland tumefaction recedes. The receding gland pulls with it the attached esophagus and occasions a pouch in the inner wall of the gullet. Traction diverticula are relatively rare. They are best demonstrated with the patient in a recumbent oblique position rather than in an upright posture.

Carman speaks of deep-seated diverticula. The topic calls for no lengthy discussion, as there are no special criteria to distinguish deep-seated diverticula from any other sort. There can be no doubt that one source of error for failure in the x-ray elicitation of diverticulous sacs rests with the fact that the pouches are food-filled at the time of ingestion of the opaque mixture. Obviously, there being no room for the opaque mixture in the already filled sac, the pouch is not demonstrated with the x-ray. It would seem desirable to effect esophageal lavage prior to the administration of the acacia mixture in the x-ray study of diverticula.

Stricture of the Esophagus.—One classification of the causes that may lead to esophageal stricture is the following:

Congenital stenosis: (a) Complete, (b) Aero-fistulous.

Cicatricial: (a) Irritant poisons, (b) Specific infection, (c) Healed ulcers.

Tumefaction: (a) Intrinsic (cancer, or other tumor), (b) Extrinsic (aneurysm or other enlargements).

Congenital stenosis of the esophagus may assume complete occlusion of the lumen when the middle of the tube becomes a fibrous cord-like structure. A more common congenital form is that in which the lower part of the esophagus opens into the trachea or one of the bronchi. Both forms are recognized at an early stage, the one by the pronounced and extensive constriction, the other by the invasion of the bronchial tract after feeding bismuth into the esophagus.

Cicatricial stenosis may result from irritant poisons. If there is any characteristic in the x-ray pathology of an irritant poison cicatrization it is that of the extent and irregularity of the lesion.

Of course, in mild cases only irregularity remains. Specific inflammations such as tuberculosis and syphilis present nothing that is particularly diagnostic. The scars that result from healed ulcer are local. They are manifested as irregularities in the lumen of the esophagus. Stenosis of the esophagus may come from tumefaction by reason of the growth of tumors in the wall usually of cancerous nature. Cancer of the esophagus will be considered under a separate caption. There may be external pressure bearing on the esophagus and leading to stricture. Usually, external pressure causes only a displacement of the gullet. When the esophagus rests against a resistant structure and an extrinsic tumor bears upon it, compression stricture may result. It is usually possible immediately to identify the fact that the esophageal contraction is the result of extrinsic pressure.

Cancer of the Esophagus.—The site of cancer is more common as the cardiac orifice is approached. That is, they are exceedingly rare at the pharyngeal introitus, more common near the tracheal bifurcation and still more common in the cardiac portion. To elicit an esophageal cancer the x-rayist depends upon changes in the outline of the tube and upon the amount of obstruction present. When the obstruction is marked one sees a tortuous irregularity of the stenosed lumen. Occasionally, antiperistalsis may be noted about the point of constriction. Early cancer unaccompanied by marked obstruction is more difficult to detect. One must depend upon irregularity of outline, which irregularities must be carefully differentiated from other filling defects that may sometimes be present. Cancer of the esophagus is most usually epithelioma. The disease is not too common. It is more frequent in males than in females and it may be observed in quite young persons. It appears to be first confined to the mucous membrane. The cancer gradually increases and soon ulcerates. The crater of the ulcer lends irregularity to the outline of the gullet. Sometimes the ulcer crater can best be visualized if the patient is in the horizontal position. As the ulcer forms, the lumen of the tube becomes narrowed; but where the ulceration is extensive stricture may sometimes be less marked. The ulcer may perforate the trachea or a bronchus, the lung, the pleura, or any of the adjacent structures. By the x-ray picture the position of the ulcer and stricture may be determined. When the growth is very dense it may cast a radiolucent or even radiopaque shadow.

Not uncommonly the only x-ray sign is that of some degree of obstruction; and a certain diagnosis can be made only after considering carefully the clinical features of the case.

Other tumors of the esophagus are rare. Their x-ray features are not distinguishable from the pathology that would be produced by carcinoma.

Extrinsic Tumefaction.—Esophageal compression may result from external pressure. Aneurysm is especially guilty in this respect and should always be considered as a possible cause of stenosis. It can be detected by either plate or screen study.

Less frequently new growths in the neck, mediastinum, or lung may expand so that they bear on the esophagus and cause its compression. Enlarged glands may act similarly. The diagnosis of these conditions has already been considered in its proper

place and it is sufficient to remark that the x-ray can often be of positive benefit.

Rupture of the Esophagus.—Rupture of the esophagus may occur under circumstances of prolonged or violent emesis. The rupture may take place at a site near the scar of an ulcer where the wall is weakened. The condition is extremely uncommon and calls for no comment.

THE CONTRIBUTIONS OF THE PRESS TO THE LAY CONCEPT OF MENTAL ILL-HEALTH.

BY DONALD A. LAIRD,

IOWA CITY, IOWA.

RESEARCH ASSISTANT, UNIVERSITY OF IOWA.

ALL animals exhibit a fundamental trait of inquisitiveness which is termed curiosity. Especially is this true of the animal which we are conceited enough to designate as the human animal. In childhood this curiosity of the human animal is exercised much after the curiosity of the primates. Objects are handled and picked apart, things tasted and smelled. The curiosity of youth, on the other hand, takes issue not so much in the properties and qualities of things as in his own abilities and powers. This shifting of the center of curiosity in youth contributes to the popularity of athletic sports and other tests and provings of abilities both general and specific.

In the adult human the expression of curiosity is perhaps not so plainly evident, but it is present and is a very potent factor in the life of the organism. One might be led to think that in the adult curiosity is outgrown because it is uncommon to find an adult taking time-pieces apart to see what makes them tick, or tasting and smelling pebbles to discover their gustatory and olfactory qualities. We do find adults, however, picking the body apart piece by piece to find out how it is put together—the anatomist; examining its functions to ascertain just in what manner it works—the physiologist; or experimenting with its integrated behavior—the psychologist. What do these pursuits serve to satisfy, aside from all pragmatic considerations, but this instinctive curiosity?

With the advance toward maturity the sphere of human curiosity is thus once again seen to shift even as the impersonal inquisitiveness of the child emerged into the personal curiosity of the youth. This curiosity of maturity has two characteristics which distinguish it from the other stages of curiosity. It is more thoroughgoing, tending even in the unscientific minded to approximate a degree of scientific thoroughness, though, unfortunately, seldom with a corresponding degree of scientific accuracy and reliability. The curiosity of the adult also serves more practical ends than in childhood and youth. It is the basis of most everyday working hypotheses. To borrow terms from the field of physical science, or medicine, for that matter, we may say that in the long run of humanity adult curiosity is an applied rather than a pure function. It is exercised, in the adult, for the guidance of the entire organism rather than to satisfy the single function.

For our purposes we may also distinguish two

general trends which curiosity may follow. It is usually introverted^{*} and directed primarily toward facts and situation which center primarily around man, as in medicine, education, sociology, and the humanistic subjects. It may also be projected so it centers not primarily in man and his environment as it affects him, but into the environment itself and for its own sake, as in pure geology and mathematics. By and large, however, the introverted type is the more common. Mankind is usually interested in (that is, curious about) its own welfare and happiness. Man is interested in things as they affect him; he has his own welfare and pleasures to further and his inquisitiveness is chiefly directed toward influences that have to do with his own well-being and functions. Man's curiosity about his own well-being is reflected in the popularity of patent medicine and health secret brochures, family "doctor books," and the syndicated medical advice of the newspapers. Man's curiosity about his functions is limited in the main to two, namely, the sex function and the function that is more or less erroneously termed mind.

It is with the fundamental curiosity which is manifest toward the nature and functions, but more especially toward the disorders, of the mind with which this article is concerned. There are perhaps no other functions of the human organism which, to the layman, are as mysterious and still as practically interesting as the mental functions. And at the same time there is no group of diseases so dreaded and so universally feared as mental diseases.[†] Neither is there a group of diseases which is so commonly avoided in discussion as mental disorders and which are still intrinsically an object of great curiosity to the human mind.[‡] The main avenue through which the layman's inquisitiveness regarding mental ill-health is satisfied is the press. All other avenues, such as personal observation, preconceived notions, frank discussion, and so on, are subsidiary to this mode of satisfying one's curiosity in this case.

This contribution rests upon the thesis that in satisfying man's propensity for knowledge concerning the functioning of his mind in health and ill-health the information given should possess several characteristics which may be summed up under the caption of *wholesomeness*. That the present conceptions are undeniably unwholesome I have demonstrated in the first reference given above. That wholesome concepts are essential is a prominent conviction under which the National Committee for Mental Hygiene is forwarding its great work. In the concepts of mental ill-health it seems that the following factors are elements which contribute to wholesomeness: first, accuracy; second, the information should be presented with no unwarranted elaboration which would tend to overemphasize cer-

*The terms introverted and projected are used not in a psychoanalytic sense but as convenient phrases which best convey the distinction which is being made.

†For a justification of this statement and other statements in this paragraph see my article "Does there exist a need for a program of education in mental hygiene?" *Mental Hygiene*, iv, 2, April, 1920, pp. 393-403.

‡Some of the more influential reasons for this I have already indicated. See "Psychopathic Nursing" in the *American Journal of Nursing*, xx, 9, June, 1920, pp. 685-689.

tain points or permit of groundless interpretations by the reader; third, the information should be broadly representative of all the facts available, not playing up a few overt characteristics; fourth, the information should not savor of the supernatural or of the mysterious; fifth, the connotations should be such as to cause no vicarious transfers of unpleasant associations; sixth, factual and theoretical interpretations should be made only by one well qualified.

With this prolegomenon in mind, the four leading papers in point of influence as well as circulation in Iowa City were carefully clipped for a period of one month extending from November 15 to December 15, 1920. The papers, with the numbers of news and editorial items pertaining to mental health found in each, are given in the following table:

TABLE I.

1. The Chicago Tribune	27
2. The Cedar Rapids Republican	14
3. The Des Moines Register	12
4. The Iowa City Press-Citizen	12
Total	65

A person taking all these papers thus is seen to have an average of about two items a day on the topic of mental health. A subscriber taking only one of the above papers, on the whole, would have access to only one item of this nature every alternate day. This hypothetical subscriber to one paper only may reasonably be taken as the type. The paper with the largest circulation (1) and emanating from the largest center has double the items touching upon our subject.

It is plainly evident that our hypothetical subscriber to one newspaper has his concepts of mental ill-health refined and enlarged by the influence of his press. Not a week passes without several items which by their news nature, as is shown in the following paragraph, and their intrinsic appeal to curiosity are read and add their cumulative contribution to the lay concepts. It is our chief purpose at present to determine if this contribution of the press is wholesome as measured by the six criteria listed above.

There were 13 of the 65 items of sufficient news and interest value to make the first page. Out of the 65 items 3 were of an editorial nature, and of the 62 straight news items and features 57 carried headlines, one item, indeed, having a seven-column flare in 72-point type across the entire front page bore the message: "REFUGEES SLOWLY GOING INSANE!"

As causes of mental ill-health we glean the following with the frequency indicated:

TABLE II.

Advancing age	4
Brain pressure	1
Confinement	1
Drink	2
Gassing (war)	1
Glands, neck	1
Glands, thyroid	1
*Gout, internal	1
Headaches	1
Lack of food	1
Strain, financial	1
Strain of world war	1
Strain of railroad life	1
Sunstroke	1
Worry	2
One item stated mental ill-health to be not inherited.	

*Internal gout was stated to cause 20 per cent. of mental ill-health.

sions: Inaccuracy is most prominent in the cases of goiter (see especially the footnote to the table), headaches, lack of food. Reportorial elaboration is responsible for most of the causes given under strain and worry, apparently, out of consideration to the family reputation, trying to advance some cause which will dispel the popular delusion of organic degeneracy as the infallible cause of causes. This list of causes is decidedly misrepresentative; advancing age being the most prominent in point of numbers, while in point of emphasis the endocrine glands of the neck perhaps surpass age. It is well known, outside of the laity, that in the experience tables of institutions these causes are not nearly so influential as this month's reading would lead one to believe. In only one instance was there evidence of the interpretations or the information having been prepared by one qualified; this was in the instance of the statement that mental ill-health is not inheritable, which appeared in the health column of one of the papers. Even this statement is both true and false, but in a way may have been fair mental hygiene in dispelling worries, and at the same time poor mental hygiene in not emphasizing the seriousness of heredity. The statement regarding the causal role of goiter was made by an evangelist whom one would have expected to place the responsibility on drink rather than on the relatively offenseless thyroid.

There was little agreement in the items regarding onset and prognosis. Two items stated mental diseases were recurrent, one that the reason was recovered in time, and another (contributed by a lawyer) that it was incurable. The onset was variously described as sudden and gradual.

In the matter of symptoms we find the material particularly rich. For convenience they will be grouped in the three groups as given in Table III.

TABLE III.

<i>Subjective:</i> Mind hazy; unable to think; headaches; gloomy; lapse of memory; sleepy; funny thoughts.
<i>Objective:</i> Dangerous; raving maniac; suspicious actions; staring into space; no emotion; go without food; invent things; actions.
<i>Criminal:</i> Suicide (15 times); murder (10 times); wife beating; forging (2 times); attack on children; bigamy; burns buildings (3 times); enticing to murder; lewdness.

The accuracy of many of these symptoms as indicating mental disease is decidedly questionable as well as indefinite. Again, a tendency on the part of the reporters to elaborate must be recorded, as many of the items carried internal evidence of a serious inharmony of symptoms. The facts are not broadly representative in view of the emphasis the objective and more especially the criminal receive. One must commit suicide before any evidence of mental disease is obtained or be murdered before it is discovered that he is living with one in poor mental health. Several instances of unwarranted interpretations are seen in the items which carry a heading such as "Commits Suicide While Insane," while the item itself tells only of the suicide, with not a single reference to the mental condition. Such is the headliner's art, and the statement made earlier in this report regarding the interest in mental ill-health is mirrored in this capitalization of it to create news-value.

Seven items brought out the point that the mentally ill were legally irresponsible, and one item that in one State mental sickness was a cause for divorce.

Applying our criteria of wholesomeness to the above list of causes, we reach the following conclu-

In one instance a physician from a State hospital testified that it was possible for a person to be sane on business matters while eccentric to the point of abnormality on others.

In a recent minor experimental study* I have determined the connotative value of certain terms in use in the field of mental health and disease. For example, the term *lunatic* was the most repulsive, disagreeable, and disliked, while the term *insane* was not quite so low in connotative value and in general more desirable than *lunatic*, but still less desirable than *mental*, which in turn was less desirable than *nervous*. Arranging some of the terms used in the news items in the order of their connotative value with the least desirable (as experimentally determined) at the top, with the frequency of their use in items, we obtain Table IV.

TABLE IV.

Lunatic	1
Insane, insanity	31
Mental disease, aberration trouble, failing.....	12
Nervous	3
Psychiatric	1
Psychopathic	8
*Crazy	5
*Madness	2

*I have not the connotative value for these terms.

The above data indicated that the terms which have the most repulsive feeling-tone are most in use. And those are the terms which, from the approach of wholesome conceptions, should not be used.

Even the news-value of such terms is questionable, for not only do they create a feeling of repulsion for the subject with which they are used, but there may be a transference of this uncomfortable feeling-tone to the general situation or elements of it, and the repulsion may fasten itself on the newspaper or on the chair in which it is read. The continual use of these terms *lunatic*, *insane*, and *crazy*, however, does tend to fixate the affective state on the topic of mental ill-health itself, and this disagreeable emotional tone which enters into the lay concept is undoubtedly influential in creating a mild repression which is responsible to some extent in hindering a frank and open formation.

To summarize.—The role of natural curiosity in the formation of concepts of mental functioning has been indicated and the place of the press in satisfying this curiosity pointed out.

It was found that the contributions of the press are inaccurate, unrepresentative of the true conditions, and presented with undesirable connotations. Moreover, there is an undue amount of elaboration of the facts in this topic and of unwarranted interpretation by illy qualified persons in the publication and editing of news items.

*"Some factors involving the mental health of the community," to be read at the August, 1921, conference of the Minnesota State Board of Control.

Sudden Death from Caseous Degeneration of the Adrenals.—Cneyx and Ragot report two cases of sudden death which proved on section to have been due to tuberculous degeneration of the adrenals. Research before death as to the presence of hypoadrenia had proved to be negative. Both patients had died suddenly without any prodromes, while in less sudden deaths attributable to the same cause we find collapse, the simulation of acute irritant poisoning, or "dry cholera," and the picture described by Sergent.—*La Presse Médicale*.

Medicolegal Notes.

Payment Under Contract with Employer May Exceed Amount in Compensation Act.—In an action by a physician and surgeon against an employer of labor to recover the value of hospital services and medicines, it appeared that the services were rendered at the request of the defendants, a firm, to one Boltz, one of their employees, who was injured while in their employ. The defendants and Boltz were both within the scope of the Minnesota Workmen's Compensation Act, which made it the defendants' duty to provide Boltz with medical and surgical supplies up to \$100. The defendants contended that a contract to pay more than that amount would not be implied from a request to perform this service, and that the verdict of \$325 could not be sustained for more than the amount fixed by the act on theory of an express contract. The Minnesota Supreme Court sees no good reason why the defendants might not agree to furnish medical and hospital attention and supplies to their employee in excess of their statutory obligation, if they saw fit to do so, and no reason why they might not obligate themselves to pay the plaintiff the full value of such services, furnished to their employee at their request. The question was: Did they so obligate themselves? The evidence on behalf of the plaintiff was, in substance, as follows: The plaintiff testified that Rasmussen, one of the defendants, called him and that, while they were on their way to attend Boltz, the plaintiff asked, "What about my pay?" and that Rasmussen said: "We carry insurance; we get our money from the insurance company, and then we pay you; you don't need to worry about that." The fact probably was that neither party thought or knew of the limitation of the Compensation Act. The court thought the jury might construe the language used as a contract to pay the value of the services the plaintiff should render to Boltz. The plaintiff was permitted to say that he performed his services on the credit of the defendants and not of Boltz. This was held proper. The defendants offered proof tending to show that he gave credit to Boltz. This was a material question in the case. It was proper that the plaintiff should testify, directly, to whom credit was given. This is within the general rule that, whenever the motive, belief, or intention of any person is a material fact to be proved, it is competent to prove it by the direct testimony of such party. Verdict for the plaintiff was affirmed.—Collins v. Joyce et al., Minnesota Supreme Court, 178 N. W. 503.

Death from Blood Poisoning Through Gum After Extraction of Tooth Not Accidental.—Death through injury to the gum, caused by the pulling of a tooth which made a port of entry for bacteria into the circulatory system and directly resulted in blood poisoning, was held not within a policy insuring against "bodily injury through accidental means exclusive of all other causes." It was not alleged that the tooth was pulled by accident, nor that any accident happened while the tooth was being pulled. The means by which the gum was injured were intentionally and purposely applied. The insured knew that the inevitable result of pulling the tooth would be to break down and lacerate the gum tissue. It was the result that followed the pulling of the tooth and the laceration of the gum tissue that was unlooked for, unexpected and unforeseen. There could be no inference from the allegations that there was any accident in connection with the pulling of the tooth.—Ramsey v. Fidelity & Casualty Co., Tennessee Supreme Court, 223 S. W. 841.

Sufficient Indictment of Unlawful Sale of Cocaine.—The Circuit Court of Appeals, Ninth Circuit, holds that an indictment charging the defendant with purchasing, selling, dispensing, and distributing cocaine in and from a certain tin box, which was not the original stamped package containing said cocaine and having in his possession said tin box containing cocaine, which did not have affixed thereon appropriate tax-paid stamps as required by the Harrison Narcotic Law, states an offense under section 1 of the act, making such purchase or sale, except from original stamped packages, an offense, and the possession of unstamped packages prima facie evidence of such offense.—Dean v. United States, 266 Fed. 694.

CERTAIN CLINICAL MODALITIES OF INFLUENZAL LUNG PROCESSES AND THEIR TREATMENT.

AMONG the very numerous manifestations of influenza which arise in the respiratory apparatus those most ordinarily met with can be grouped under the following modalities: A more or less generalized bronchial catarrh, pulmonary congestion with disseminated foci, pneumonia and bronchopneumonia, splenopneumonia with slow resolution, and complicated forms of pleural empyema. To these clinical types it is proper to add the hypertoxic form with more or less latent pneumonic foci, the asphyxic form with progressive edematous congestion, the prolonged form with persisting congestion, all serious processes; while among the mild forms should be mentioned delayed bronchopulmonary signs and the prolonged form with successive foci.

The hypertoxic form with more or less latent pneumonic foci gives rise to a temperature around 104° F., with marked prostration. Dyspnea varies in degree, cough and expectoration are slight, but the sputum is apt to be blood-stained. Auscultation reveals a few discreet rales over a limited area and obscure respiration. There is massive albuminuria and Hay's reaction is positive. The situation remains thus for some time with a temperature at a high level; the pneumonic focus reveals itself or remains latent. The dyspnea becomes more marked, likewise the blood in the sputum, epistaxis occurs, the tongue becomes dry, and vomiting or diarrhea develops. There may be delirium, and in spite of the good quality of the pulse the patient dies on the third to the eighth day, usually fully recognizing the gravity of his illness.

The asphyxic form with progressive edematous congestion gives rise to a high temperature, marked oppression, cyanosis of the lips and face, paroxysmal coughing, and if there is any expectoration whatsoever, it is frothy and pink. Auscultation reveals subcrepitant rales soon filling both lungs. This condition lasts a few days with a temperature around 104° F., and when improvement from bleeding does not continue, the edema returns, a true pneumoplegia takes the place of active congestion, albuminuria arises, Hay's reac-

tion becomes positive, the heart weakens and death occurs from progressive asphyxia.

In the prolonged type the lungs are filled with subcrepitant rales which resist the ordinary means of revulsion, the temperature varies between 101° and 103° F., and prostration is great. Cough is severe but with little expectoration. These patients die suddenly or death results from progressive dyspnea.

In mild forms with a delayed pulmonary focus or successive foci the prognosis is good. In the former there is no albuminuria and Hay's reaction is negative; the pulse is good, although asthenia is considerable. The temperature drops, but two or three days later bronchopneumonia develops and must be looked for.

Expectoration varies in these various forms of influenzal lung processes. It may be nil or very slight without influencing the prognosis, but the same cannot be said in the case of the hypertoxic or pseudophymic forms and in pneumonia or bronchopneumonia, because here, the absence of expectoration indicates paralysis of the lung. Bloody sputum, hemoptysis and dyspnea are serious symptoms, while nausea, vomiting and severe diarrhea belong to the severe forms of influenzal lung processes. Icterus is not favorable from the viewpoint of prognosis. Hyperazoturia is common but is not always related to uremia or albuminuria. The liver is markedly involved in these cases, generally being the enlarged yellow liver. Albuminuria is usual and when massive or progressive indicates that the situation is serious. The syndrome of renal insufficiency often combines with that of hepatic insufficiency, and they should be detected without delay, as they control both prognosis and treatment. Hypotension is the rule in influenza and appears to be dependent upon suprarenal insufficiency. The heart usually keeps up but the blood pressure and state of the myocardium should be watched. If the former progressively drops it is a bad sign. Occasionally the cardiac and suprarenal insufficiency become associated toward the end of the lung process and the patient dies from these late occurring phenomena. Delirium, tremor, and mental disturbances are of bad omen, and if the temperature remains at 104° F. without oscillations the outlook is bad. This also applies to temperatures between 101° and 103° F. which continue for more than ten days without remission. When the temperature goes up after an apyrexia of three or four days, it indicates the development of new congestive foci, while a progressive rise after complete apyrexia of some duration implies that a complication in the pleura is taking place.

To sum up it can be said that the lesions are in the lungs but the danger resides in insufficiency of the liver, suprarenals and kidneys, as well as the severity of the general infection.

In the hypertoxic forms of influenzal pulmonary processes a fixation abscess and colloidal metals are our most potent therapeutic measures. The latter should be given intravenously. In the asphyxic form bleeding to extent of from 500-600 c.c. is indicated

and a bad prognosis should be made when the blood does not flow freely or does not coagulate. Should the pulmonary edema recur bleeding should be repeated in two or three days. For paralysis of the lung strychnine is quite as active as any drug. Should the hepatorenal syndrome become evident—massive albuminuria, positive Hay's reaction—urotropin by mouth or intravenously is indicated, while marked asthenia and hypotension require adrenalin subcutaneously at first and later exhibited by mouth. Strychnine, sparteine and comphorated oil are the best cardiac stimulants, especially the latter given intravenously, in doses of 2 to 4 c.c. morning and evening.

NONSURGICAL TREATMENT OF CANCER.

DESPITE our ignorance of the nature of cancer it is possible to lay down certain generalizations concerning it which will stand every test in practice. In the *Bulletin général de thérapeutique* for January, 1921, clxxii, 1, Albepsy undertakes to set some of these forth, drawing upon recent works by A. Robin, Lumière, and Laumonnier. We are justified, he says, in the assumption that the cells of one subject are not entirely identical with those of another, although he may be of the same species, or even near of kin. Such an individual quality has to be considered in connection with a disease like cancer. In some individuals there is a special reactivity toward certain agencies, so that proliferation occurs more readily. It is taken for granted that in a cancer subject a point of lowest resistance must have been present—else of course there would be a far greater number of multiple primary growths. The tumor thus formed need not be malignant but the presence of a cancerogenous factor may cause it to become such. At the same time this cancerogenous agent may cause the appearance of cancer *de novo*. According to these theses we cannot expect to cure cancer by the knife but may hope to reach it by serotherapy and especially autoserotherapy. The first conclusion that the cells of each individual have their own special reactivity is applicable to the whole of disease. Two individuals of the same race, sex, age, etc., will show individual reactions in pneumonia, in typhoid fever, and in anaphylaxis. In a so-called cancer family the type of cancer may show the greatest variability. There are, of course, entire races which show immunity toward cancer. The primitive negro who seldom has cancer is by no means free from benign growths, and he has a special predisposition to fibroma and keloid. We have, therefore, to bear in mind that this sclerogenous tendency may antagonize the proliferation of the cancer cells, as seen especially in schirrus of the breast in old and spare women.

That cancer appears by preference at the point of lowest resistance is well known, although surgeons speak simply of precancerous lesions or areas of irritation. But when they say that the growth results from trauma or chronic irritation alone they go too far—else every excessive smoker would have

cancer. There is a *tertium quid* in addition to the lowered resistance associated with the cellular autonomy of the individual. The mere chemical or mechanical irritant is not necessarily the cancerogenous agent, Albepsy thinks, for first we must fully exclude the existence of some low form of life such as excites the production of tumors in plants and perhaps in certain animals. Without the presence of a constitutional factor it is difficult to understand the relations of benign to malignant tumors: for either type of growth may exist without reference to the other, or the benign growth may become malignant—while conversely under treatment a malignant growth may apparently become benign. We know that simple irritation will cause benign growths in predisposed subjects and areas; but to cause cancer in a benign growth some special causal agent would seem requisite. When a cancer has become passive and innocuous under radiation it suggests that this special cause has been inhibited for the time.

Since cancer is due so largely to the patient's individuality, the author says, we are forced to think that a curative agent can come only from the patient himself; which view is strengthened by the few recorded cases of spontaneous cure and numerous others of cure from various forms of nonsurgical treatment. For autoserum the author suggests the patient's own blood serum with or without the addition of an extract of the cancer itself. Lumière, who is working along this line in his laboratory, expects soon to report his results.

In view of the great activity shown in recent years in the study of endocrinology it is not surprising that the hormone therapy of cancer has received some attention. This is not strictly new, for the use of thyroid extract was recommended many years ago by Dr. Robert Bell as an adjuvant in the nonsurgical treatment of cancer, but it has received fresh impulse of late. About a year ago Dr. Naamé, a well known practitioner of Tunis, published a volume on cancer under the term "dyscytogenesis." The conception of the author of the nature of cancer was that it was such as should respond favorably to otophary. There is a lack of harmony, he says, between cytopoiesis, or cell production, and cytolytic, which may call for the exhibition of what he terms eutrophants or substances which make for normal growth. The cases selected by him to test his views were apparently mostly superficial epitheliomata, occurring especially in old men and women. For women he prescribed thyroid and ovarian extracts, while the men got thyroid and testicular extracts. In a case of anorectal cancer in a very old woman he gave a mixture of thyroid extract, dried bile, and pancreatine. He believes that with pluriglandular therapy something can be done for cancer. To thyroid, which is the corner stone of all treatment, he would add other extracts, depending on the seat and character of the disease. Mammine would be indicated especially in cancer of the breast with thyroid and ovarine. Men would require thyroidine, orchitine, and perhaps the substance of the organ in which

the cancer had developed (he goes no further than to suggest suprarenal extract in malignant tumors of that origin). The author has learned that Dr. Sajous of the United States holds ideas on the opotherapy of cancer which resemble his own, but understands that this endocrinologist gives suprarenal extract in all cancer. Korschewsky has recently shown an experimental basis for the influence of the endocrines on cancer development.

A SIMPLE PROCEDURE FOR AVOIDING ANAPHYLACTIC SHOCK.

ANAPHYLACTIC shock can be avoided, as Roux, Bessredka, Banzhof, and Fumelener have shown experimentally, by inducing hypnosis before the injection is given, by means of chloralose, chloral, or urethane. More recently still, Kopaczewski and the Roffos have noted that it was possible to prevent the production of acute anaphylactic accidents by means of ethereal solutions without going to the extent of producing anesthesia and these observers have attributed the preventive properties of all these substances to a common physical character they present, namely, that of decreasing the surface tension of the serum. They came to the conclusion that in the future all influence of the nervous system that has been supposed to exist in the genesis of anaphylactic shock is to be discarded, as this phenomenon depends principally on a reaction of colloidal flocculation and asphyxia correlated to occlusion of the capillary networks by aggregations of micellæ. Although regarding with reserve the part that these observers attribute to surface tension in the production of anaphylactic shock, Lumière and others have for some time suspected that the serum injection provoked the formation of a precipitate in the blood plasma which might be the initial cause of the phenomena observed.

This explanation is in accord with the well-known fact that when an animal is prepared by the injection of foreign albuminoid matter its serum at the end of a few weeks acquires the property of producing flocculation in the solution of albumin employed. It is therefore logical to suppose that the hemoclastic paroxysm induced by the secondary injection of this same albuminoid matter in the prepared animal is attributable to the formation in the blood of a precipitate susceptible of profoundly disturbing the capillary circulation. Richet, by injecting an untreated animal with a mixture of the blood of a sensitized animal and the substance giving rise to the paroxysm, obtained the usual results. Briot, Friedberger, Friedmann, and several others have also provoked anaphylactic shock by treating normal animals with mixtures of sera reacting on each other and giving rise to flocculation.

In order to verify the above hypothesis, Lumière and Chevrotier have carried out a series of experiments with the attempt to discover the chemical combinations capable of preventing the production of this flocculation. They injected sheep's serum into an ass in small but repeated doses, and forty days after the last injection the ass was bled and

the serum obtained was distributed in tubes to which various substances, including sheep's serum, had been added in order to determine those which prevented mutual precipitation of the sera. Contrary to what they expected, these observers found only a very few reagents susceptible of fulfilling this condition, the precipitate being remarkably insoluble in almost all the bodies assayed, and of those which they thought would be the best—sodium sulphocyanide, sodium ethylsulphate, and sodium hyposulphite—had not the power of absolutely preventing all precipitation.

On account of its low toxicity, sodium hyposulphite appeared to be the best of all for the prevention of anaphylactic shock, and in order to be assured of the exactitude of this supposition these observers prepared two lots of guinea-pigs by injecting into each 1 500 c.c. of normal sheep's serum. Thirty days later the animals composing one lot being taken as control animals were given an intracardiac injection of $\frac{1}{2}$ c.c. of the same serum to which was added $\frac{1}{2}$ c.c. of an 8:1000 isotonic solution of sodium chloride. Without an exception they all died in one or two minutes, after presenting paralysis of the hind legs and convulsions. In the animals comprising the second lot prepared in the same way, the NaCl solution was replaced by the same volume of a 5 per cent. solution of sodium hyposulphite and it was found that no anaphylactic accident occurred. The serum in the dose which had produced shock in the control animals gave rise to no symptom. The same experiments were repeated with antidiphtheritic serum and gave exactly the same results. Sodium hyposulphite does not appear to destroy or even attenuate the properties of the antitoxic sera, and these observers are now undertaking experiments to ascertain the influence of a prolonged contact of these bodies, with the object of demonstrating that no ill-result ensues from the use of such mixtures. They point out that they have not yet determined the action of sodium hyposulphite so far as late anaphylactic accidents or secondary serological effects are concerned, but from the results so far obtained they maintain that we now have a simple and entirely safe means of preventing anaphylactic shock.

THE DRUG LAW MUDDLE.

In a recent report of the Committee on Drug Evil of the State Magistrates' Association, Judge Collins reviews the muddled situation as it now exists in this State, and makes some suggestions for finding a way out. Since the Magistrates' Association is in a measure responsible for the present unsatisfactory law, it is very proper that it should now be endeavoring to correct the mistake then made. The report suggests that the law itself is good and indeed necessary, since it claims that the Harrison law could accomplish little or nothing in the way of repression of the evil. Then why not, in the name of all that is decent and seemly, repeal the Harrison law? Are there not enough useless and worse than useless laws already without retaining

this oppressive measure! But this only by way of parenthesis. As a matter of fact the Harrison law works fairly well—far better than the New York law—in some of the neighboring States, and if we must have one let us put up with that. But two laws are at least one too many. "It was believed," Judge Collins says, "that the Commission of Narcotic Drug Control would work out so well that any of the inadequacies of the law could be modified or changed by regulation. It seems, however, that regulations were adopted, from time to time, which aroused the intense resentment of the medical profession and the drug trade, both wholesale and retail, and undoubtedly revived peddling in the so-called underworld, and caused a great increase in the number of cases coming into the Courts, and tended to the discouragement and disgust of practising physicians and apothecaries, almost to the extent of preventing practice or prescribing."

One of these measures was the monstrous Fearon-Smith bill, supported for some perhaps inscrutable reason by the representative of the Medical Society of the County of New York, which would forbid physicians to treat drug addiction outside of institutions. Another absurd measure introduced at the same time would give legal force to the false statement that drug addiction is a communicable and pestilential disease.

The Committee does not favor the repeal of the State law for the reason, as before said, that it thinks the Harrison law could not be enforced in the State, and that under it peddling and the distribution of drugs would exist in its worst form. Judge Collins therefore in this report recommends the drafting of a bill abolishing the Department of Drug Control which has so bungled the enforcement of the law, but retaining the essential provisions of the State Law. In spite of the fact that the Magistrates' Association has before given bad advice, as the sequel has proved, it might perhaps be well to give it a chance to redeem its error, and when the new attempt fails, if it does, the way will be open to do away entirely with the State law; and then, if the Harrison law is as ineffective as Judge Collins thinks, that too may be repealed. The situation would then be no worse than it is now and might be far better—at least as good as it was before the present laws gave an impetus to peddling and led to the deliberate manufacture of drug addicts among school children in order to increase the profits of the illicit sales.

CERTAIN NEW METHODS OF TREATING EPILEPSY.

It is of course not pretended that curative remedies have been found for epilepsy but there is always room for improvements in the control of the seizures. Christin of Geneva has an article on this subject in the *Schweizerische medizinische Wochenschrift* for February 3, 1921, li, 5. He refers first to the salt free or salt poor diet which is now old, but which serves to indicate what constitutes a real advance in treatment. Along the same line is the constant effort to get relatively nontoxic bromide—containing synthetics and

bromine substitutes. The author does not seem convinced that any real advance has been made in the former field. In 1912 the introduction into practice of the veronal derivative known for short as luminal has resulted in a very extensive tryout of the latter and reports show that it not only quickly antagonizes the seizures but diminishes the post-convulsive confusion. The drug is rapidly eliminated and may be taken for weeks and even months without disagreeable by-effects. It has no power over *petit mal*. One may lessen the dosage of bromine by mixing with luminal. All in all the author regards it as a distinct advance compared with salt-poor diet, but naturally it is in no sense curative. The former use of borates has led to the introduction of a boricitrate of potassium which, it is claimed, can cut down the number of major attacks and change them to *petit mal*; and then reduce the number of the latter. This points at first sight to a curative property but time shows that this singular power is only transitory. The author has tested this salt side by side with luminal, and prefers the latter. He concludes with the latest recommendation to use strychnine in heroic doses (Hartenberg). The results claimed have not yet been confirmed.

SUCCESSFUL TRANSPLANTATION OF THE ILEOCECAL VALVE IN THE DOG.

CAUCCI publishes a preliminary communication on this subject in *Il Policlinico*, February 7, 1921, xxviii, 6. The author desired to make a termino-lateral implantation of the ileum with the valve into the colon, leaving the valve intact with the aim of watching its behavior. He wished to determine whether it would conserve its functions in its new situation. He excised a collaret of colon 5 mm. from the mouth of the ileum and then resected the cecum and implanted the ileum with valve termino-laterally in the descending colon. The function of the transplanted valve was tested by injecting water into the rectum at a constant mercury pressure under radioscopic control. In the five experiment dogs the valve was found to be intact and able to function normally in its new position. The highest pressure tested with the mercury manometer was 15 cm.—more than the valve in its normal position in the cadaver withstands. In the early days after operation there was some inhibition of the sphincteric action of the valve, while section of the small intestine or mesentery close to the valve abolished the function of the latter.

News of the Week.

Medicinal Distribution of Beer and Wine Regulated.—Tentative regulations for the prescribing of beers and wines for medicinal purposes, made public on April 7, are as drastic as could possibly be imposed under the terms of the Palmer ruling. The text of a summary of these regulations places the limit of beer which may be prescribed for any patient in any monthly period at 4 1/7 gallons, or two glasses a day, of wine at 3 gallons. The patient is entitled to get this maximum amount from only one physician and may not lawfully accept and have filled a prescription from another physician. Only

physicians may issue these prescriptions and only druggists may fill them, and both will be held to strict accountability for prescriptions issued and filled. Brewers and wholesale druggists may not employ registered pharmacists to fill prescriptions. A physician may not fill prescriptions for his own use. Only a duly qualified brewer or wine maker may manufacture beer or wine for medicinal purposes and on the property where the manufacture is specified. This new measure is very elaborate and contains a great deal in the way of detailed instruction. Emphasis, however, is laid on the fact that these regulations are merely tentative. Commissioner Williams is delaying their approval on the theory that his tenure of office is uncertain and that a new commissioner who would have the duty of enforcing these regulations should have the right of approving or disapproving them.

Christian Science Legalized in Nebraska.—A bill legalizing the practice of Christian Science was passed by the Nebraska House of Representatives on April 7. The bill subjects Christian Scientists to the State quarantine laws. An amendment to make the practice subject to the State public health laws failed. The bill has not yet been signed by the Governor.

Higher Tax on Alcohol.—A new revenue bill has been proposed by Congressman Good of the Appropriations Committee which includes a provision to increase the tax on alcohol used in the preparation of medicines to such an extent that the price of alcohol would be four times that before the war. This would make the cost of tinctures excessive, if not actually prohibitive.

Comprehensive Organization of Medical Interests Proposed.—At the stated meeting of the Medical Society of the County of New York, held on March 28, Dr. Byron C. Darling introduced resolutions calling attention to the many medical problems demanding solution; the fact that the medical profession had allowed things to drift until they had neither the information, the plan, nor the machinery to meet their problems, and that there were in New York sixty more or less scattered independent medical societies without an interlocking organization. The resolutions make the following recommendations for dealing with the situation: (1) the appointment of a commission to make a comprehensive survey of medical practice including National and State Health Departments, charity organizations, hospitals and dispensaries, Chambers of Commerce and civic associations, industries, industrial insurance companies, etc.; (2) the establishment of a weekly news organ either separately or by arrangement with a weekly journal already in existence; (3) the appointment of an executive secretary in common for the State and County Societies, or one for each, inasmuch as the duties of these offices are too burdensome for the active practitioner of medicine.

Governor Miller Would Oust Hospital Commissioners.—Formal charges of inefficiency and unwillingness to cooperate with the State Administration in its effort to achieve efficiency and economy, were served by Governor Miller against Dr. Charles W. Pilgrin of Poughkeepsie and Dr. Frederick A. Higgins of New York. According to press reports the only offense of the hospital commissioners was a protest against a reduction of the appropriations

to the State Hospitals, which they believed would result in a lowering of the standard of medical care and nursing service. The New York Psychiatric Society, at its meeting on April 6, adopted resolutions in the form of a telegram to Governor Miller protesting against his demand for the resignation of the Commissioners and requesting that he defer action until a full investigation can be made in connection with which the society has offered its co-operation. It has also requested the Commissioners to withhold their resignations for the present. In addition to the New York members out of town members signing the protest were: Dr. Adolph Meyer, Johns Hopkins University; Dr. C. MacFie Campbell, Harvard; Dr. A. Ross Diefendorf, Yale; Dr. Stewart Paton, Princeton, and Dr. Henry A. Cotton, Trenton, N. J.

Henry Phipps Institute Establishes Diagnostic Clinic.—A diagnostic clinic for the examination of employees is about to be opened at the Henry Phipps Institute in Philadelphia, under the direction of Dr. Frank A. Craig. The clinic will be neither a charity nor a money-making scheme but will be conducted entirely at cost. The Phipps Institute is equipped to conduct health surveys for any plant, to examine its men and to act in an advisory capacity, particularly for industries which have their own medical service but wish expert opinion on special cases. The group of physicians associated with the new clinic is composed of the following: Dr. H. R. M. Landis, Dr. Frank A. Craig, Dr. John S. Scouller, Dr. Walter E. Lee, Dr. Robert M. Luykens, Dr. Thomas B. Holloway, Dr. Henry K. Pancoast, Dr. Hugh Miller, and Dr. Charles C. Norris.

New Medical Regiment for New York Guard.—A new medical regiment to be attached to the Twenty-seventh Division, New York National Guard, is in the process of reorganization. It will be known as the 102nd Medical Regiment and its headquarters will be those of the present sanitary train at the armory at 56 West Sixty-sixth Street. The regiment will consist of the following: The Second Ambulance Company of Rochester, redesignated as the 104th Sanitary Company; Third Ambulance Company, New York, reorganized as the 104th Ambulance Company; Fourth Ambulance Company of Syracuse, motorized ambulance company, to be the 105th Ambulance Company; Third Field Hospital, Brooklyn, redesignated the 104th Hospital Company; Second Field Hospital, Albany, redesignated 105th Hospital Company.

Opera Singer Sues Doctor.—A suit to recover \$100,000 damages for alleged disabilities resulting from an operation have been filed by Octave Dua, formerly of the Metropolitan Opera Company, against a New York surgeon. The plaintiff claims that as the result of an operation on his nose he had lost the sight of one eye and been otherwise seriously disabled. The defendant has filed a general denial of the allegations.

Two New Typhus Cases.—Two new cases of typhus fever have recently been reported in Brooklyn, N. Y., both in natives of Russia who have been in this country for some years. The Health Department has been unable thus far to trace the source of the infection.

Dr. Antonio Fanoni of New York City has received word from the Italian Secretary of State of

his promotion by the King of Italy from the rank of chevalier to officer in the Order of the Crown of Italy, in recognition of his services during and subsequent to the war.

Dr. George Goodrich has tendered his resignation as Secretary of the State Board of Health and Superintendent of Public Health of Arizona to take effect as soon as a successor can be appointed.

Dr. Eugene Chimene has been elected county health officer of Guilford County, N. C.

Dr. L. Emmett Holt has resigned the Carpenter professorship of diseases of children in the College of Physicians and Surgeons, Columbia University, to accept the appointment of clinical professor of diseases of children. He will continue to give clinics at the Babies' Hospital as in former years.

Dr. Thomas J. Cummings has resigned as head of the State Hospital at Phoenix, Arizona.

Dr. A. Goldman Retires from the Presidency of the Bronx Hospital.—On Sunday evening, March 27, a dinner was tendered by the board of directors of the Bronx Hospital to Dr. Alexander Goldman, its retiring president. Dr. Goldman has held the position of President of the Bronx Hospital for ten years. He resigned the presidency of the Board and is taking up his duties as chairman of the executive committee of the Medical Board. In the appreciation of his services, the directors of the hospital at the dinner presented him with the proper set of resolutions and endowed a ward in his honor to be called the Dr. Alexander Goldman Medical Ward.

American Legion Demands Hospital.—Claiming that afflicted world war veterans should not be made to suffer because of the State retrenchment plans, the American Legion posts of the State have begun vigorous action to deter the Legislature from abandoning construction of a hospital for insane veterans. Assemblyman James T. Carroll will introduce a bill providing for the State construction of a hospital as provided for by a bill passed last year, appropriating \$3,000,000 as the State's share of the cost of construction of such a hospital to be located at Creedmoor.

Professor Joseph Jastrow of the University of Wisconsin will read a paper on "The Psycho-Pathology of the Belief in Spirits," at the New York Academy of Medicine, 17 West 43rd Street, on the evening of April 22. The lecture will be illustrated by unusual lantern slides showing the historical side of the belief and the theories by which its recent support has been guided. The meeting is under the auspices of the Eastern Medical Society of the City of New York.

The Western Electrotherapeutic Association will hold its third annual meeting in Kansas City, Mo., April 21 and 22, 1921.

The American Institute of Homeopathy will meet in Washington, D. C., June 19-24, 1921. Dr. Frank A. Swartwout is chairman of the local committee on arrangements.

Doctors, Dentists and Druggists Organize.—Waukegan and North Chicago doctors, dentists, and druggists met on March 26 and formed a temporary organization. Dr. C. S. Ambrose was elected president, and Dr. W. Stanford Pearce secretary.

The Lancaster County (Pa.) Medical Society

was organized at a meeting held in Lancaster, March 28, 1921, and the following officers elected for the ensuing year: *President*, Dr. R. C. Brown; *Vice-President*, Dr. J. D. Funderburk; *Secretary*, Dr. S. L. Allen.

An Artificial Limb Manufacturers' Association has been formed by twelve houses in this branch of industry which were called to Washington at the time of our entrance into the war to consult with the Council of National Defense. The Council warned them of the necessity of preparedness in order to give skilful aid to returning soldiers who had lost one or more limbs. Membership is stated to be open to all reputable manufacturers of artificial limbs in this country and Canada, and the Association has appealed to the medical profession to give support only to its members.

Obituary Notes.—**Dr. HASSO A. MEILIKE**, a graduate of the Sioux City Medical College, in 1888, died at his home in Clintonville, Wis., on March 29, at the age of sixty-six years.

Dr. JAMES F. CROWLEY of Batavia, N. Y., died suddenly of heart failure on March 20, at the age of sixty-one years. He was a graduate of the University of Buffalo Medical Department in 1885, and had held the positions of village health officer and village physician of Batavia.

Dr. HERMAN E. LUCAS died at his home in Champlin, Minn., on March 11, at the age of seventy years.

Dr. ALFRED HAKANSON of Chicago, died in Mobile, Ala., on March 23, at the age of fifty-four years. He was a graduate of the University of Nebraska Medical College in 1890.

Dr. S. A. STERRETT METHENY, a graduate of the University of Michigan in 1889, and of Jefferson Medical College in 1894, died at his home in Philadelphia on March 26, at the age of fifty-one years. He was a member of the Royal Microscopical Society of London and served for some years as a medical missionary in Syria.

Dr. FLETCHER BLAGBORNE, a graduate of the Michigan College of Medicine in 1883, died at his home in Marine City, Mich., on March 16, at the age of sixty-six years.

Dr. JULIET E. HANCHETT, a graduate of the Woman's Medical College of Pennsylvania in 1885, died at her home in Syracuse on March 29, at the age of sixty-four years.

Dr. DAVID KINDLEBERGER, a medical director in the United States Navy, retired, died at his home in New York on March 6, at the age of eighty-four years. He was appointed assistant surgeon in the Navy in 1859, and at the time of his retirement, in 1896, was the oldest medical officer on the active list. During the course of his service he had charge of the Washington Naval Hospital and served as a member of the Medical Examining Board of the Navy.

Dr. JOHN JOSEPH LEARY of Utica, N. Y., died of diphtheria in New York City on March 18, at the age of thirty-three years. He was a graduate of Syracuse University Medical Department in 1916, and was a member of the United States Army Medical Reserve Corps during the late war.

Dr. JOHN MARTINZA CARDEZA, a graduate of the Long Island College Hospital in 1906, died from pneumonia at his home in Brooklyn, N. Y., on

March 30, at the age of forty-one years. He was a visiting surgeon at the Long Island College Hospital, and in the service of the Metropolitan Life Insurance Company.

Dr. GEORGE F. COTT of Buffalo, died on March 22, at the age of sixty-six years. He was graduated from the University of Buffalo Medical Department in 1884, and shortly afterward became professor of otolaryngology in this institution. He was a Fellow of the American College of Surgeons, a member of the American Triological Society, and a Major in the Medical Reserve Corps of the Army during the world war.

Dr. IRVING I. WALLACE of Syracuse, a recent graduate of the University of Pennsylvania Medical Department, died suddenly in a local hospital on March 24.

Dr. AUGUSTUS H. CONSON of Gainesville, Tex., a graduate of Bellevue Hospital Medical College, in 1874, died on March 29, at the age of seventy-two years.

Dr. BARTLETT L. PAINE, of Lincoln, Neb., a graduate of the Medical College of Ohio, Cincinnati, in 1875, died from cerebral hemorrhage, on March 13, at the age of sixty-nine years.

Dr. SAMUEL PRITCHARD FETTER, a graduate of the Miami Medical College, Cincinnati, in 1904, died at his home in Ashland, Ky., on March 8, at the age of thirty-eight years. He was at one time president of the board of health of Ohio, and local surgeon for the Chesapeake and Ohio Railroad.

Dr. RUDOLPH MENDER of San Antonio, Tex., a graduate of the University of Leipzig, Germany, in 1874, died, on March 15, at the age of sixty-nine years. He was formerly city physician of San Antonio.

Dr. A. T. SLEMONS, a graduate of the University of Tennessee Medical Department, in 1888, died suddenly of heart failure at his home in Clinton, Tenn., on March 29, at the age of fifty-five years.

Dr. SAFFORD R. HAMER, formerly city physician of Cincinnati, Ohio, died at his home in Denver, Colo., on March 25, at the age of seventy-four years. He was a graduate of the Medical College of Ohio, in 1868, and a Civil War veteran.

Dr. PHILIP N. MATLOCK of Masonhall, Tenn., a graduate of the University of Nashville, in 1866, died, on March 25, at the age of seventy-eight years.

Dr. W. P. BERRY, for many years a practising physician in Memphis, Tenn., died at Pasagoula, Miss., March 23, at the age of eighty-seven years.

Dr. GEORGE RICHARD HILL of Kandall, Wis., a graduate of the Bennett Medical College, Chicago, in 1886, died of a complication of diseases, on March 18, at the age of sixty-nine years.

Dr. ELBRIDGE GERRY CARPENTER of East Greenwich, R. I., died after a long illness, on March 30, at the age of seventy-one years. He was graduated from the Medical Department of the University of Vermont, in 1874, and afterward studied in Jena, Leipzig, Berlin, and Vienna. He was a former president of the Kent County Medical Society and a member of the Rhode Island State Medical Society and the American Medical Association.

Dr. KARL R. MELOY of Detroit, Mich., a graduate of Wittenberg College with the degrees A.B. and A.M. in 1902 and 1905, and of Johns Hopkins Medical School, in 1906, died on March 30, at the age

of thirty-nine years. He was made director of the Grace Hospital Laboratories, Detroit, in 1914, and was professor of bacteriology and pathology at the Detroit College of Medicine and Surgery.

Dr. GEORGE H. POST of Fithian, Ill., a graduate of the Eclectic School of Medicine, Cincinnati, in 1876, died of cancer of the stomach in a hospital in Danville, Ill., on March 10, at the age of seventy-four years.

Dr. R. T. OLMSTED of Versailles, Ind., a graduate of the Medical College of Ohio, Cincinnati, in 1879, died as the result of injuries received in a fall, on March 25, at the age of seventy years.

Dr. FRANK GARTEN, a graduate of Albany Medical College, in 1908, died at his home in the Bronx, New York, after a short illness, on April 4, at the age of thirty-nine years.

Dr. JAMES A. DALE of Houtzdale, Pa., a graduate of the College of Physicians and Surgeons, Baltimore, in 1895, died from cerebral embolism, on March 11, at the age of fifty-nine years. He was a member of the Medical Society of the State of Pennsylvania.

Dr. SAMUEL THOMAS WEIRICK of Washington, D. C., a graduate of the University of Maryland, Baltimore, in 1865, died in Los Angeles, on March 16, at the age of seventy-seven years. He was a retired Captain in the Medical Corps of the United States Army. He served as a private in the First Ohio Volunteers in the Civil War, as captain and assistant surgeon of volunteers in 1901, was appointed Lieutenant, M. C., U. S. A., in 1908, and was retired with the rank of captain.

Dr. HARRY J. HARTZ, a graduate of Jefferson Medical College, in 1908, died of acute indigestion at his home in Philadelphia, on March 31, at the age of thirty-eight years.

Dr. SEWELL S. HEPBURN, JR., of Annapolis, Md., a graduate of the Medical College of Virginia, Richmond, in 1897, died suddenly of heart disease on April 5, at the age of forty-seven years.

Dr. J. A. WHITE of Portland, Ore., a graduate of the Charity Medical College, New Orleans, in 1873, died on March 27, at the age of seventy-one years.

Dr. JOHN BENJAMIN ROE of Oregon, Ill., a graduate of Bennett Medical College, Chicago, in 1895, died from the effects of being gassed during the war, in a Chicago hospital, on March 28, at the age of forty-nine years. He served as lieutenant in the army medical service and was gassed while working in close proximity to the firing line.

Dr. DANIEL WEBSTER YOUNG, a graduate of Hahnemann Medical College, Chicago, in 1899, died at his home in East St. Louis, Ill., on March 20, from heart disease, at the age of fifty-three years. He was a Major in the M. C., U. S. A., being in charge of the x-ray work in a number of field and general hospitals in France and Germany.

Dr. WILSON D. WALKER, of Kelloggsville, Ohio, a graduate of the Pulte Medical College, Cincinnati, in 1895, died of pneumonia, on March 16, at the age of fifty-two years.

Dr. ROBERT W. GLAUBIT, a practitioner of Brooklyn, N. Y., for more than thirty years, died suddenly of heart disease at his home in Rockville Center, L. I., on March 27, at the age of fifty-six years. He was a graduate of New York University Medical College, in 1888.

Correspondence.

OUR LONDON LETTER.

(From Our Own Correspondent)

LONDON, March 22, 1921.

Tuberculosis Bill.—The Parliamentary Correspondent of the *Daily Telegraph* states that the object of the Public Health (Tuberculosis) Bill to be introduced by the Minister of Health is so to meet the altered situation that there shall be no break in the provision made for the treatment of tuberculosis when sanatorium benefit ceases on April 30. The bill proposes to transfer to the county and county borough councils the responsibility for providing institutional treatment for tuberculosis which, under the provisions of the National Health Insurance Act of last year, is to be taken from the insurance committees so far as insured persons are concerned. A large majority of the county and county borough councils have already made arrangements for the institutional treatment of tuberculosis within their areas, and the bill imposes no fresh obligation upon these councils so long as their schemes remain in operation. A very small proportion of the total number of councils has not yet made sufficient provision for the treatment of tuberculosis, and the bill provides that if any of these councils fail to make adequate arrangements the Minister himself may make such arrangements as may be necessary for the purpose and recover the cost from the council. Other provisions are designed to facilitate cooperation between councils in the exercise of their powers for the treatment of tuberculosis and to enable them to place on their tuberculosis committees or subcommittees, persons, including members of insurance committees, who are not members of the council. With the exception of the few cases in which the council has not yet made adequate provision for institutional treatment of tuberculosis, the bill imposes no additional charge upon the rates. It is proposed that the councils should receive the same financial assistance in aid of this service as they have received in the past under the old arrangements.

Venereal Disease in the British Army on the Rhine.—Sir. L. Worthington Evans stated in Parliamentary Debates the other day that the incidence of venereal disease in the British Army of the Rhine was not satisfactory, and had been the subject of much anxious consideration ever since the area was first occupied. During the first quarter of 1920 the ratio admitted to hospitals for venereal disease was 45.81 per 1,000 of the strength. The ratio of the last quarter of 1920 was 40.22; and for the month of January last it was equal to a quarterly ratio of 37.80.

Science and Crime.—At the Society of Arts, London, on March 16 last, Mr. Charles Ainsworth Mitchell read a paper on "Science and the Investigation of Crime." Mr. Mitchell showed in his paper how the development of science and its many branches had narrowed down the criminal's chances of escape since the early days of last century, when anyone who committed a secret crime had an even chance of evading capture. He suggested that mistakes of identity had been

a more fruitful source of miscarriages of justice than all other causes put together. The world contained some 400,000,000 of people (this is surely an underestimate), and notwithstanding the infinite variety of human features, there was hardly anyone alive to-day who could not be mistaken for someone else. He concluded that no one could hope to keep in touch with all the branches of science, and what was wanted was a certain degree of coordination among scientific workers so that new methods most suitable to any particular problem might be immediately applied. Sir Basil Thomson, Assistant Commissioner of Metropolitan Police, said that for the five years, 1903 to 1908, there were in Paris (population 2,500,000) 737 murders, in London, 106 murders, and in Chicago (2,000,000 population) 693 murders. The comparison was striking and a curious thing was that the number of arrests in respect to these crimes was nearly the same in each case, viz., 60 per cent.

Vital Statistics of 1919.—The Registrar-General's Report for England and Wales for 1919 has just been issued. During this year the birth and death rate conditions were far removed from the ordinary. In the first half of the year the birth rate fell to the lowest point on record, but in the latter part of the year it recovered considerably. The death rate for 1919 was the lowest on record with the exception of the rates for 1910 and 1912, and this notwithstanding the heavy mortality from influenza in the spring. It may be noted that in 1919 the cancer death rate was the highest yet recorded in England and Wales. The report states that the statistics of 1919 support the general belief that the best criterion of the health of a people consists in the mortality in the earlier days and weeks of life. In 1919 there were comparatively few deaths of infants under one year of age. The rate was 12.2 per cent. In 1901-10 the percentage was 22.6. Infant mortality as regards total births, was equal to 89 per 1,000, and was 15.2 per cent. below the average in the ten years immediately preceding. The increased mortality of the first four weeks after birth is shown by statistics in this report to be limited to the first two, the third and fourth having remained almost stationary. As for the causes of infant mortality it may be gathered from an analysis of the figures in the report that in each period after the first four weeks the mortality from the principal causes, except influenza and respiratory affections, was lower in 1919 than in the years immediately preceding the war. A distinctive feature of the report is that in the rural districts of the north of England there is a great excess of infantile mortality exceeding that of the northern towns, great or small. In 1919 mortality during the first five years of life was very small in England and Wales. Although influenza raged during the spring of 1918 and largely raised the mortality among children under five years of age in that year, the corresponding mortality in 1919 was extremely low. In 1919 mortality in the second year of life was lower than in any other of the past few years and therefore almost certainly the lowest yet experienced.

The Pathology of Influenza.—At a recent meet-

ing of the Pathological Section of the Liverpool Medical Society the discussion was resumed on Professor J. G. Adams's paper, which was published in the *Lancet* January 1, last. Dr. J. M. Buchanan opened the discussion and dealt with the subject from the clinical side. He stated that during the epidemic of 1918 about 450 cases of the disease from among the U. S. A. troops were admitted to three of the British auxiliary hospital, to which he was appointed consulting physician. The outbreak was serious. It soon became evident that the cases could be divided clinically into four groups: (1) The mild catarrhal type. (2) The pneumonic type. (3) Cases with physical signs of bronchiolitis. (4) Cases of profound toxemia with little or no respiratory phenomena in whom coma-vigil was the rule, and who with few exceptions died. Among the complications profuse epistaxis was not uncommon. Empyema was somewhat rare, but occurred in prolonged cases. A few developed otitis media and some mastoid abscess. Subcutaneous abscesses were not uncommon. When arthritis occurred it was generally in the knee. Symptoms of meningitis were present in a few cases, and be understood that in such the pneumococcus was present in the cerebrospinal fluid. His clinical observations of the recent epidemic led him to the conclusion that we had to deal with a triple or multiple infection process. Professor Ernest Glynn quoted some experiences of the influenza epidemic among the American soldiers in Liverpool; direct films from the sputa of 13 cases showed pneumococci and influenza groups in five, influenza groups in two; 22 post-influenza empyemas showed pneumococci in nine, streptococci in eight, pneumococci and streptococci in one, pneumococci and *staphylococcus aureus* in two, streptococci group in one, while one was sterile; blood cultures from 70 cases showed pneumococci in nine, pneumococci and streptococci in two, influenza group in two. A mixed influenzal pneumococcal and streptococcal vaccine which he had made was used extensively for treatment of the American troops, but he had no reliable data as to its value. As "influenzal pneumonia" was often accompanied by septicemia, vaccines seemed inadvisable on theoretical grounds.

The Treatment of Cancer.—It appears that cancer has increased in Great Britain during the past few years and in consequence a good deal of solicitude is being expressed with regard to treatment which in many respects is by no means satisfactory nor encouraging. The possibilities of radium in this direction are a frequent subject for discussion, and on March 8 last the Minister of Health was asked in Parliament whether his attention had been called to the recent increase of deaths from cancer; whether he had any committee or officers in his department who were making any inquiries into the cause of and cure for this disease; whether the department made any financial grants to any hospital or institution which was providing research work or special wards and treatment for this disease, and if not, whether, in the interest of the community and the need for combating this scourge he would favorably consider granting financial help to any

such hospital or institution. Dr. Addison, in reply, said that he very much regretted to state that the number of deaths attributed to cancer continued to rise. He pointed out that an extensive research into the causes of the disease had for some time past been undertaken by the Imperial Cancer Research Fund and the Medical Research Council were facilitating research into the possibilities of radiotherapy and had been the means of providing a substantial quantity of active radium salt for the purpose. Cancer research funds were relatively well supported from voluntary sources, and he did not think that the issues were sufficiently clear for him to recommend grants in aid of the cost of the treatment of this disease at the present time.

Large Radium Purchase.—At the annual meeting of the Manchester and District Radium Institute an appeal was made for funds to carry on the work. It was pointed out that the demand for radium was becoming greater. The subcommittee decided in view of the urgency of the matter to purchase some 200 milligrammes of radium element for £6,000. This will give the institute 1,300 milligrammes.

The Question of Vitamines.—The public here are beginning to take an interest in the matter of vitamins, despite the fact that some medical men think that their value in a diet has been somewhat exaggerated and too much importance has been paid to the subject of late. In the House of Commons the other day the Minister of Health was asked whether any and what steps were being taken to bring to the knowledge of the public the fact that vitamins, which constituted a necessary part of any sound diet, were essential to the diet of the young, and could be secured by utilizing whole cereals and whole pulses, fruits, salads, and vegetables, and whether he would publish and disseminate as soon as possible a short practical leaflet which, without advocating any special system of diet, would draw attention to the value of these wholesome and economical foods. Dr. Addison replied that he was considering whether it would be practicable to issue any statement on the subject. Any such statement would, of course, contain as full a reference to the part played by vitamins in nutrition as the present state of knowledge of the subject would permit. He drew attention to the remarks on vitamins contained in the Report of the Chief Medical Officer of the Board of Education published in 1919. In connection with vitamins Dr. Jane Lane-Claypon, an authority on children's diseases and who has investigated the vitamin question from the standpoint of milk, gave a lecture at King's College in the early part of March, in which she discussed milk vitamins. She emphasized the fact that these substances were of greater value to the growing child than to the adult. She pointed out that in winter when cows were fed on cake, etc., the amount of vitamins in milk was markedly less than in summer, when the cows were out at grass. Prolonged heating was more likely to cause vitamin destruction than a sharp but rapid process of heating, and especially to that vitamin which was most essential to the maintenance of good health in the

growing child. The essential vitamine was still present in dried milk, though somewhat diminished in amount as compared with raw milk. The other two vitamins were relatively stable to heat and there was no evidence to show that they were destroyed by ordinary domestic processes. The large number of questions put to the Minister of Health in Parliament show that intelligent interest is being taken in questions of health and that the Ministry of Health was not only needed but has to a great extent justified its existence. The Department of Health has been subjected to bitter criticism by a section of the lay press, but on the face of it a great deal of this criticism has been undeserved. Perhaps the worst that can be said of the Ministry is, to use American slang, that "it has bitten off more than it can chew," and that possibly its policy tends to bureaucratic methods, which are opposed to the instincts and traditions of the British race.

Progress of Medical Science.

Boston Medical and Surgical Journal.

March 31, 1921. clxxiv, 13.

1. The Rat in Health and Economics. Mrs. Albert T. Leatherbee.
2. Modifications of Technique in Gall-Bladder Surgery. G. Forrest Martin.
3. Energy Requirements of Girls from 12 to 17 Years of Age. Francis G. Benedict and Mary F. Hendry.
4. Bornhardt's Formula. H. Gray and F. B. Allen.

2. Modifications of Technique in Gall-Bladder Surgery.—G. Forrest Martin holds that cholecystectomy is the operation of choice in all but a very limited field, such as elderly patients who must have prompt relief with a minimum shock; gross septic conditions which can be more safely handled by preliminary drainage, with complete operation later, and the like. The field of operation is better exposed, the bowels are kept out of the way more easily, the patient is quieter because less disturbed by manipulations with the transverse than is the case with any other operative method. Vomiting, straining, and other post-operative efforts tend to pull the incision tighter instead of apart, and thus the final wound is stronger. Closure of the wound without drainage bids fair to be an accepted procedure in a great majority of cases. Experiments show that this is a safe procedure even in the face of positive germ cultures.

3. The Energy Requirements of Girls from 12 to 17 Years of Age.—Benedict and Hendry complete this series of reports of studies conducted through the Nutrition Laboratory of the Carnegie Institution, and summarize their findings as follows: 1. The average, minimum, resting pulse rate per minute of girls from 12 to 17 years of age, just before rising in the morning, was found to be 81 at 12 years, 77 at 13 years, 77 at 14 years, 83 at 15 years, 71 at 16 years, and 74 at 17 years. 2. The insensible perspiration for these girls per kilogram of body weight per hour was as follows: 0.72 gram at 13 years, 0.71 gram at 14 years, and 0.77 gram at 15 years. 3. The respiratory quotients of groups of 12 girls each, about 7 to 8 hours after a light meal, were 0.81, 0.81, 0.78, and 0.79. 4. The caloric requirements of young girls during 10 hours of "bed rest" was on the average 55.0 calories per individual per hour. 5. The average 24-hour basal heat production of groups of girls from 12 to 17 years of age was 1250 calories per individual, irrespective of age. 6. The heat production per kilogram of body weight per 24 hours decreases regularly with increasing age from 29.9 calories at 12 years, 2 months, to 21.7 calories at 17 years. The curve indicating the general metabolic trend is throughout its entire length materially below the few scattered observations of earlier writers. 7. The heat production per square meter of body surface per 24 hours likewise decreases, but not so regularly, with increasing age, ranging from 928 calories at 14

years to 745 calories at 16 years. 8. The metabolism of groups of young girls can be predicted from the general curve indicating the heat production per kilogram of body weight referred to age to within an average error of ± 3.1 per cent. The prediction for the heat production per unit of body weight is somewhat better than that per unit of surface area. 9. The curves representing the heat production per kilogram of body weight referred to weight and per square meter of body surface referred to weight for these groups of girls from 12 to 17 years of age blend with remarkable uniformity with similar curves based upon the measurement of a large number of normal girls from birth to 12 years of age. 10. No influence of puberty or the prepubescent stage is clearly proven in any of the results.

2. The Interpretation of Blood Pressure Variations. With Observations on Normal Pressure Variations and the Relation of the Adrenals and the Autonomic Nervous System to the Production of Blood Pressure.—Homer Wheelock details certain experimental observations relative to the production and control of a normal pressure, and applies the physiological principles derived therefrom as interpretative measures in a consideration of the clinical variations of blood pressure. The range of blood pressure variations compatible with a normal economy is illustrated by readings made upon sixty-six normal medical students and twenty-two aged women. Marked variations in blood pressure were found between the two groups as a whole and in the individuals of the same group in various postures and following exercise. The writer discusses the influence of the heart, of the vasomotor apparatus, and of chemicals on blood pressure, and in conclusion calls attention to the value of blood pressure determinations. The sense of security suggested by accepted figures as indicative of normal states is not entirely warranted in the interpretation of blood pressure variations. A standard average normal blood pressure for a given age and sex is entirely desirable, but individuals equally normal, as far as is discernible, may show widely different readings. Hence, a known individual variation is easier of interpretation and becomes of more absolute importance than a comparison of a given reading with a given standard normal. From a purely physiological point of view a pressure which is found to be higher or lower than the accepted average normal should not, in itself, be considered pathological but rather as the pressure normal to the condition in which it is found. The fact that a given blood pressure reading is high or low cannot be construed to mean other than that one or more of the factors involved in its production, maintenance and control have become accentuated or depressed. A blood pressure determination, therefore, can only mean the figures obtained by the use of the instrument; the indications of such figures, however, depend directly upon the interpreter's experiences and his understanding of the factors involved in the production of such figures. The usual classification of blood pressure readings as indicative of hypertension, hypotension, or isotonic states, is a workable convenience, but if one accept the given standard as correct then all individuals fall into one of these three

groups irrespective of the usual or normal condition of the individual case. The extremes of variation in any compiled set of figures undoubtedly represent unusual conditions, also rapid changes from the individual's usual standard are indicative of disturbed functioning. It appears, however, that a thorough search for the cause of such variations, both direct and indirect, should be excited because of blood pressure findings rather than assume that the patient's ailment has unfolded itself through the cuff of a sphygmomanometer. Blood pressure variations are not disease conditions *per se*, but rather symptoms indicative of an altered bodily economy. In many cases blood pressure variations are indicative of compensatory phenomena and therefore should not be interfered with. Hence it appears that the safest interpretation of blood pressure variations will follow as the result of a careful evaluation of the processes involved in the production, maintenance, and control of a balanced circulation.

3. **Factors in Reactions After Blood Transfusions.**—Butsch and Ashby studied seven hundred and thirty-seven transfusions with the object of explaining the reaction to transfusions. They employed the sodium citrate method described in detail by Pemberton and Hunt. Certain factors connected with the technique of transfusion were studied, and were not found to be factors in the transfusion reactions observed. Patients with normal temperatures and patients with more nearly normal hemoglobin percentages are less likely to have reactions. An increased tendency to reaction was not found when transfusions were given in series. *In vitro* evidence of incompatibility between blood of properly grouped donors and patients was not found; neither did the patients show *in vitro* evidence of incompatibility of blood for their own groups with repeated transfusions. The incidence of transfusion reactions was not affected by fasting.

4. **The Value of the Pneumothorax Treatment of Pulmonary Tuberculosis.**—Ernst P. Boas holds that treatment by artificial pneumothorax is a valuable adjunct in the handling of selected cases of advanced pulmonary tuberculosis in which other measures have been of no avail. It frequently gives temporary symptomatic relief, and very rarely brings about a cure. In lung abscess its dangers outweigh its possible good effects. Six cases are cited.

3. **Diagnosis of Pregnancy by the Roentgen Ray: Possibilities of the Procedure During the First Half of Gestation.**—Bartholomew, Sale and Calloway undertook this study with the object of determining the earliest stage of gestation at which a diagnosis of pregnancy could be made by demonstrating portions of the fetal skeleton by the roentgen ray. The total number of roentgenograms taken was twenty-four. The earliest stage of pregnancy attempted was at two and one-half months; the latest stage about the end of the sixth month. From the end of the second to the end of the third month, one roentgenogram was taken and was negative. From the end of the third month to the end of the fourth month, five roentgenograms were taken and all were negative. From the end of the fourth month to the end of the fifth month, ten roentgenograms were taken and three were positive. From the end of the fifth month to the end of the sixth month,

eight roentgenograms were taken and four were positive. The earliest positive result, then, was obtained at four and one-half months.

8. **Unusual Manifestations of Heroin Intoxication and Symptoms of Withdrawal.**—Alfred Gordon reports a case in point. An analysis of the muscular manifestations during the phase of gradual withdrawal of heroin leads to the diagnosis of tetany. The contractions were bilateral and intermittent like those in tetany, but close observation reveals that there were at no time contractions of the fingers, with the attitude (obstetric or writing), very frequently found in tetany. Tests were not made for the varied signs characteristic of tetany. The muscles of the body were simultaneously involved and their contractions were frequently repeated; they were almost of a continuous character. The resemblance to tetany consisted in their tonic character, but they were of greater intensity. The phenomena during the period of withdrawal of heroin presented great similarity to those of epilepsy, but they were not completely identical.

9. **The Auricular Heart Sounds.**—William D. Reid makes the following assertions: 1. The sounds produced by auricular systole are faint and may often be below the level of audibility. 2. Systole of the auricles is marked by two sounds, which are related to its initial phase and termination just as the first and second heart sounds are to the contraction of the ventricles. 3. As the contraction of the auricles is not sustained after the maximum tension has been achieved, the auricular second sound follows almost immediately on its first sound. 4. The second sound produced by the contracting auricles, namely, that due to the closure of the auriculoventricular valves, occurs during the auriculoventricular intersystolic period. 5. The filling of this intersystolic period by the auricular sound is suggested as a more reasonable explanation of the well-known fact that the auricular sounds are never detected save in cases of heart block, when the auricular contractions may occur well separated from those of the ventricles.

2. **Further Notes on the Intravenous Injection of Antimony Tartrate. Leucoderma and Skin Complications: Administration of Large Doses.**—J. B. Christopherson states that a few grains of antimony tartrate (5-8 gr.) by intravenous injections may be sufficient to cure leishmaniasis of the skin, more (20-30 gr.) are necessary, as a rule, to bring about a cure in bilharziasis, and still more (60 gr., perhaps more) are necessary for leishmaniasis or kala-azar, and possibly still more (probably in repeated courses) for the cure of trypanosomiasis. Antimony tartrate (pot. or sod.) when given intravenously in appropriate dilution and administered with care may be given in larger total doses than is generally supposed. The blood, considered as tissue, is probably capable of withstanding more physical and chemical ill-use than any other organ; but owing to its structure and distribution it is obviously incapable of resisting microorganic invasion, and is the logical route for direct attack upon micro-organic and other diseases, particularly those of the blood stream itself. The cure of parasitic diseases, such as bilharziasis, kala-azar, trypanosomiasis, filariasis, dracunculosis medinensis, by a drug given intravenously (the drug itself if it acts directly, or a derivative if it acts indirectly) depends on: (1) the permeability of the enclosing membrane (or skin) of the parasite; (2) the penetrating power of the drug which in turn depends on its physical condition of chemical structure; (3) the toxicity of the drug to the parasite.

6. **A Controlled Study of Sanatorium Results.**—E. Ward bases this communication on the condition of

270 sanatorium cases two years after leaving the institution as compared with the condition of 597 controls two years after commencing treatment. This period is enough to allow the increase in weight and improved appearance manifest in most patients when they leave a sanatorium to have passed off, and gives a fair comparison. To gain further information, and to check the two-year results, a further series of 121 sanatorium cases, and 282 controls, is considered after a four years' period. The controls were not sent to a sanatorium. The number of sanatorium cases lost sight of after two years is about two per cent., not sufficient to affect the result in any way. Between the two and four years, another one per cent. may have been lost. Among the control cases rather more have been excluded for this reason. The patients were classified as: Class 1.—Patients at work—90 per cent. prospect of continuing present work for a considerable time (may be considered a cure). Class 2.—Patient at work, but health somewhat uncertain—60-90 per cent. prospect of remaining at present work for a considerable time. Class 3.—Working, but health precarious—40-60 per cent. prospect of continuing at present work for considerable time. Class 4.—Too ill to work. Class 5.—Very ill. Of the 270 cases in all stages of disease, two years after sanatorium treatment 119 (44 per cent.) come under classes 1 and 2; 44 (17 per cent.) under 3; 1 (26 per cent.) were classed as 4 and 5; and 36 (13 per cent.) were dead. Three stages of the disease are recognized: (1) Slight; (2) medium; (3) extensive. Of the class 1, stage 1 cases after two years out of 102, 30 were cures (30 per cent.); after four years, 16 out of 55 (31 per cent.). Among 233 stage 1 controls after two years, 107 are counted cured (46 per cent.), and after four years 144 cases, 62 (54 per cent.). Among stage 2 sanatorium cases, after two years, a total of 153 gives 9 cures (6 per cent.); and after four years, 60 cases, 4 cures (7 per cent.). Controls at stage 2, 248 cases, after two years, yield 17 cures (0 per cent.), and after four years, 102 cases, 10 cures (10 per cent.). The writer is constrained to believe that we are too much hemmed in by tradition and authority in considering tuberculosis, and that the time has come for free thinking in this respect if progress is to be made. He suggests that steps be taken to modify sanatorium treatment with a view to improved results; also that certain sanatoriums should be reserved for isolation purposes, to which mainly cases with tubercle bacilli in the sputum should be sent, at whatever stage of disease; while others, which might be called preventoriums, should be reserved for slight cases and suspects no patient being admitted there with tubercle bacilli in the sputum. At the preventorium a patient would stay only for a short time, say a month, under convalescent home conditions, while at the sanatorium he would stay indefinitely, the longer the better.

2. Asthma and Anaphylaxis.—Frank Coke holds that half the cases of asthma can be proved by the skin reactions to be due to sensitization by foreign proteins. The technique of the skin reaction is as follows: The inside of the arm and forearm are cleaned, and a scratch one-eighth inch in length made with a scalpel, not going deep enough to draw blood. On to this the protein and solvent are placed. The tests should be an inch and a half apart. On the two arms a number of tests can be made at a sitting, though sometimes it will take three or even four hours to complete a test. A positive reaction consists of an urticarial

wheel not less than one-quarter inch across. This appears in from ten minutes to half an hour. Sometimes they are as large as a halfpenny, with irregular branches coming out of them. These reactions vary enormously in different people, so that much experience is necessary to judge the degree of reaction present. The proteins the writer uses fall into four main groups: Some 70 foods, 20 bacterial proteins, 10 kinds of animal hair, and 10 pollens; also various face powders, etc. A full test may take four sessions of an hour each. If the causes can be removed the patients are relieved of the asthma at once. Much can be done to relieve or even cure other cases which do not give positive reactions, by the usage of various proteins, as antigens, to desensitize them with. Asthma, hay fever, urticaria, eczema, migraines, epilepsy, and paroxysmal hemoglobinuria, have many common traits and will probably all be proved eventually to be symptoms of anaphylaxis and not separate diseases at all. This list will most likely be considerably enlarged.

4. Renal Decapsulation for Chronic Parenchymatous Nephritis.—Frank Kidd, in the light of more recent experience, considers a reconsideration of this procedure justified. He reports four cases, two of whom had high blood pressure and two low blood pressure. He is not convinced that, as suggested by Horder, only cases without cardiovascular change will be benefited by the operation, since in one of his patients with high blood pressure the result was very good. Of course, in this case, the raised blood pressure may only have been a temporary phenomenon, and it may be that no permanent changes had taken place in the heart or in the blood vessels. He believes, however, that something more must be learned to enable one to distinguish the type of case suitable for the operation. One favorable case had polyuria, and one had oliguria. He does not believe that the beneficial action of decapsulation has anything to do with the relief of tension. His view is that by removing the capsule of the kidney one unblocks the lymphatics and sets up another route for the lymph to flow out of the kidney. The lymphatics of the kidney run up from the ureter under the capsule through the kidney, where they receive the lymph of the kidney substance, and then to the glands in the vascular pedicle of the kidney. The capsule seems to act as a membrane to shut off the lymph from the perinephric fat tissue. Possible in these cases of chronic nephritis the lymphatics become blocked either by excess of lymph or by fibrinous deposit, and the nephritic poison cannot be drained away from the kidney substance. Kidd has noticed that directly after stripping off the capsul of these kidneys, clear lymph seems to flow out from the kidney sponge almost at once—the kidney seems to ooze lymph. This lymph may then be picked up by the tissue spaces of the perinephric fat and be absorbed by another route.

2. Painless Hypodermoclysis.—Willard Bartlett considers it remarkable that surgeons have been content with hypodermoclysis which in most instances must have seemed to the patient little short of brutal. The vicarious administration of water in his service has been revolutionized by the employment of local anesthesia from the beginning to the end of the procedure. A very extensive employment of infiltration anesthesia led to the suggestion of introducing very dilute novocaine instead of straight salt solution or distilled water.

In the evolution of the method gradually increasing amounts of fluids were used as hypodermoclysis, in which, from time to time, the percentage of novocaine was cut down first from $\frac{1}{2}$ to $\frac{1}{4}$, then to $\frac{1}{8}$, and finally to $\frac{1}{16}$ of 1 per cent., without the anesthetic value of the drug being appreciably diminished. The writer emphasizes that he is not advocating $\frac{1}{8}$ or $\frac{1}{16}$ per cent. novocaine solution in the performance of surgical operations, but he states conclusively that it suffices for the introduction of fluid under the skin. It was but a further step in the technique to add sterile morphine to the hypodermoclysis fluid. The dosage, of course, is to be determined by the rapidity of inflow, age and condition of the patient, and all the other elements which ordinarily enter into the employment of this drug. Adrenalin is added to the fluid where hypodermoclysis is used in any of the conditions, such as shock, hemorrhage, etc., which are attended by a fall of blood pressure. A constant inflow of this substance is highly desired, since its destruction is so rapid as to make the effect of each small dose of short duration. The apparatus used is the ordinary 700 c.c. glass drip bottle, a rubber tube one yard in length, controlled by a screw clamp, and a slender, long needle. This is substantially the apparatus commonly used by hospitals for the introduction of water into the rectum, with the exception that the drop sight feed attachment is cut out, since use is made of a local anesthesia agent, and the rate of inflow into desensitized tissues does not matter particularly. The inflow is regulated according to the rate of absorption, the water-logged area never being allowed to become unreasonably tight, and thus threaten tissue pressure necrosis. The site of election is found to be the flank midway between the lower ribs and the prominent upper curve of the ilium. Less subsequent damage has occurred there than elsewhere. Bartlett no longer injects fluid under the breast of a woman, because she is likely to experience a great deal of pain every time she takes a breath for some hours after the anesthesia effect of the fluid has worn off. The same thing is true of the upper arm if a fluid has been injected into the axilla or the pectoral muscles. The introduction of the needle is rendered painless by ethyl chloride spray on the skin. After the needle has been introduced the region is covered by a small square of gauze, held in place with adhesive, and the surgical aspect of the little procedure is complete. Then it remains only for a nurse, or the patient himself, if he be a very reasonable individual, to control the rate of flow.

4. **Some Surgical Aspects of Asphyxia.**—Evarts A. Graham divides this extended discussion into three parts. The first involves the following ways in which disturbances of tissue respiration in the human body may occur: (1) Interference with the intake of oxygen. (2) Interference with the normal power of the blood to carry oxygen, or to remove carbon dioxide. (3) Interference with the circulation of the blood. (4) Interference with the power of the tissues to utilize oxygen. The second part is devoted to the effects of asphyxia, and the third to the recognition of asphyxial effects. Interference with the intake of air is the result of not only obstructions of the upper air-passages, but also of pulmonary disturbances which give rise to a diminished alveolar surface. These latter disturbances are due both to changes within the lungs, such as inflammatory exudates, and to abnormal pressures outside the lungs which limit their normal expansion. The principal agents which restrict the expansion of the lungs by pressure, are air and fluid. The disturbances within the thorax which are caused by abnormal changes of intrapleural pressure are discussed from the standpoint of new experimental work, as a result of which it seems evident that the previous, commonly accepted, ideas are incorrect. From the standpoint of pressure relationships the normal thorax may be regarded practically as one cavity instead of two. Any change of pressure in one pleural cavity is accompanied by practically an equal change in the other, so that an equilibrium of pressure exists at all times throughout the whole thorax. The prevalent conceptions of pneumothorax are held to be erroneous, in that they are based on the assumption that when an opening is made into the chest one lung is collapsed and the other maintains respiration. This assumption implies that

the mediastinum constitutes a rigid partition between the two pleural cavities. On the contrary, the mediastinum in the normal thorax is so mobile that any increase of pressure in one pleural cavity pushes it over into the opposite one so that both lungs are compressed practically equally. If, on the other hand, the mediastinum has been made rigid by induration as a result of long-standing inflammation, or if it has become fixed by adhesions, then a pleural opening on one side will not produce the same pressure changes in both pleural cavities. The maximum opening into a pleural cavity which is compatible with life depends upon a definite relationship which exists between the amount of air entering the lungs and the amount entering the pleural opening. An average normal man should be able to withstand for a short time an opening of about 64.8 sq. cm. (10 square inches); one with a "vital capacity" greater than the average will be able to withstand a larger opening. There is harmony, therefore, between these results and the finding at the front that men were able to maintain respiration with gaping thoracic wounds which seemed surprisingly large. A double pneumothorax in a normal chest is more dangerous to life than a unilateral open pneumothorax merely because usually the combined areas of the two openings (and therefore the amount of air admitted into the pleural cavities) is greater than a single opening on one side is likely to be. Theoretically and experimentally effects of practically the same severity result in the case of one or more openings into one pleural cavity as follow the creation of a double pneumothorax, provided that in each case the combined areas of the various openings are equal. The bearing of these results and deductions upon both the treatment of acute empyema and upon thoracic surgery in general is obvious. Whenever the amount of air taken into the lungs is limited by the presence of an active pneumonia, with plugging of both air channels and alveoli, whenever there is an excessive demand for air, whenever there is a sufficient weakening of the respiratory muscles to impair compensation, or, in short, whenever there is a marked reduction in the "vital capacity," the size of the pleural opening compatible with life becomes smaller; and if any or all of the above factors are present in sufficient intensity, even a very small opening into the pleural cavity will produce death from asphyxia. Since all of these factors are likely to be present to a high degree during the early stage of an empyema of the streptococcus type, early operation with the establishment of an open pneumothorax carries with it an unwarrantable danger. Either a method of repeated aspiration or one of closed drainage is indicated until after the above dangerous factors have disappeared. Interference with the ability of the blood to carry oxygen or to remove carbon dioxide is of interest to surgeons chiefly in connection with anemia, both acute and chronic, and perhaps rarely in poisonings of the type of carbon monoxide poisoning. Interference with the circulation of the blood is of surgical importance not only locally in connection with the ligation or destruction of an artery, but also in heart disease, in shock, and in pneumothorax. An inability on the part of the tissues to utilize oxygen is seen especially in narcosis with common general anesthetic agents and also in intoxications with acids, cyanides, etc. The effects of the disturbances of tissue respiration are both anatomical and physiological. The former consist, in general, of the syndrome of edema, fat infiltration, hemorrhages, and necrosis. The physiological disturbances comprise the phenomena of so-called "acidosis," changes in the respiration, glycosuria, etc. The importance of an impaired kidney function as a factor in the production of an "acidosis" is emphasized. The application of these ideas to various surgical conditions, such as in surgical narcosis, in intestinal obstruction and acute dilatation of the stomach, in shock, etc., are discussed, as are likewise the principles underlying the recognition of these effects and the methods of minimizing them.

Record of 923 Prostatectomies.—G. Marion, the well-known urologist of Paris, who receives an appreciation in a recent issue of *El Siglo Médico*, has recently performed his 923d prostatectomy.

Book Reviews.

THE PRINCIPLES OF GYNECOLOGY: A Manual for Students and Practitioners. By W. BLAIR BELL, B.S., M.D., Lond., etc., Gynecological Surgeon, Royal Infirmary, Liverpool; Lecturer in Clinical Gynecology in the University of Liverpool; Sometime Examiner in Gynecology and Obstetrics to the Royal Colleges of Physicians and Surgeons, England, and to the Universities of Durham and Belfast; Arris and Gale Lecturer, and Hunterian Professor, Royal College of Surgeons, England. Third edition. New York: William Wood & Co., 1920.

IN our review of the second edition of Bell's work we commended it heartily, although war conditions had made extensive revision of the previous edition impossible. Here, however, we have an edition which has not only been thoroughly revised, but in which considerable portions have been entirely rewritten, and much fresh material has been added to the text.

The book is divided into nine parts and two appendices. Parts I and II, occupying 120 pages, deal with the morphology and the physiology of the female genital organs; and in them the foundation is laid for an intelligent study of gynecological conditions and their treatment. Part III gives a short discussion of history taking and the examination of the patient. The next five parts cover the subject proper under the following headings: Derangements of the Normal Anatomical Conditions; Disorders of the Normal Physiological Conditions in Relation to Puberty, Menstruation, Conception and the Menopause; Infective and Parasitic Diseases of the Genital Tract; Tumors; and Allied Morbid Conditions. In Part IX we find suggestions for pre- and postoperative treatment, with consideration of the principal postoperative complications, and about 90 pages devoted to the surgeon's preparations for operation, and the description, with copious illustrations, of the principal strictly gynecological operations. In this section and also throughout the book the author has not confused the reader with innumerable methods of diagnosis and treatment, but has given a straightforward description of what has served him best. In Appendix I we find a list of postoperative exercises; while Appendix II gives a very useful classification of the causes of certain gynecological symptoms and manifestations. The logical sequence of subjects, the generous use of bold faced type in the text and carefully selected page headings make reference to any particular subject easy, often without referring to the index, which, by the way, is unusually complete.

The volume itself, with its fine paper, beautifully clear, large type, and excellent illustrations, is a fine example of the bookmaker's art; but all these would be of little moment except that they form a fitting setting for an admirable text. The style is easy and graceful and the book is most interesting. In our opinion, it is one of the best treatises on gynecology extant for either student or practitioner.

SYPHILIS. By LOYD THOMPSON, Ph.B., M.D., Physician to the Syphilis Clinic, Government Free Bath House; Visiting Urologist to St. Joseph's Hospital; Consulting Pathologist to the Leo N. Levy Memorial Hot Springs, Ark.; Lieutenant-Colonel, Medical Reserve Corps, United States Army; Member of the American Urological Association and of the American Association of Immunologists. Illustrated with 81 Engravings and 7 Plates. Second Edition. Thoroughly Revised. Philadelphia and New York: Lea & Febiger, 1920.

BECAUSE of its general excellence, this work has survived its infancy and now presents a second edition. Judging from its present form, further editions are confidently anticipated. Throughout it shows most careful revision and modernization. The historical review of the disease is somewhat enlarged, as is the section on the prevalence of the malady. Attention is directed to its economic importance by quotations from the U. S. Army statistics of 1917, showing that time lost from service because of syphilis aggregated 584 years, equivalent to \$210,240 computed at the pay of a private soldier at \$30 per month. Suicides and loss of efficiency from mental anguish are factors which can-

not be calculated. Additional text appears on morphological description of the *Spirochæta pallida*, and the modes of its transmission. The author seems skeptical regarding second infections of syphilis in the same individual and sets forth criteria severely difficult to establish to prove the second infection. A new section is added on syphilis in the negro race wherein these people are shown to be infected in high percentage. A new table of classification of syphilodermata is given which is comprehensive and practical. New paragraphs are added in the discussion of the histopathology of syphilodermata, their clinical history, and diagnosis. An especially good chart is added on the differentiation of these lesions from measles, tinea versicolor, acne, eczema, dry rashes, etc. In those chapters dealing with laboratory diagnosis and findings of syphilis, the author describes his own modification of the Wassermann reaction and claims it to be simpler and more accurate than others. He damns with faint praise the luetin reaction and points out its fallacies. He amplifies the text of his first edition on syphilitic fever, life insurance considerations, involvement of the circulatory and respiratory systems. The section on syphilis of the liver and its differential diagnosis from carcinoma merits especial compliment. Adequate consideration is given in the newly written matter to syphilis of the breast, thyroid, adrenals, and other glands, as well as to the genitourinary organs. The portion given to syphilis of the kidneys and bladder is especially praiseworthy. Throughout the book "salvarsan" is changed to read "arsphenamin" and "*Treponema pallidum*" to read "*Spirochæta pallida*." Thompson pays tribute to Ehrlich as a scientist, but regrets the blot of commercialism on his name. The name of the infecting organism, *Spirochæta pallida*, is well chosen because its discoverer so called it and for the sake of unanimity of expression despite the evidence against putting it into the genus *Spirochæta*. As in his first book, the author is generous in according credit to other authorities and has chosen his illustrations with nicety of judgment.

PRACTICAL PHARMACOLOGY, FOR THE USE OF STUDENTS OF MEDICINE. By W. E. DIXON, M.A., M.D., F.R.S., Professor of Pharmacology and Therapeutics, King's College, London; Reader in Pharmacology, Cambridge; Assessor to the Regius Professor of Physic, Cambridge. Cambridge: University Press, 1920.

THIS little book is an account of experiments which a student can easily perform for himself in class in the course of pharmacology at Oxford and Cambridge. The experiments illustrate well-recognized actions of common drugs in everyday use. The book serves to bring home to the student the principles on which he can apply his knowledge in dealing with disease in actual practice and teaches him to confine his attentions to known actions and reactions in place of the extended ramifications of the vast armament of the pharmacopœias.

HEART AFFECTIONS, THEIR RECOGNITION AND TREATMENT. By S. CALVIN SMITH, M.S., M.D., Instructor in Medicine, University of Pennsylvania Graduate School, Visiting Physician to the Philadelphia General Hospital, Visiting Physician for the Study of Cardiovascular Affections, Philadelphia Hospital for Contagious Diseases. Philadelphia: F. A. Davis Co., 1920.

DR. CALVIN SMITH avowedly has not written an exhaustive work, but he has reduced to comparatively small compass the essential facts of anatomy, physiology, and pathology, with diagnosis and treatment so that the busy physician, or, still better, the senior student of medicine can get a working knowledge of recent advance. With this aim in view it is not the purpose to be critical of minutiae. The essential facts are all here and the more profound student must go to the larger and more exhaustive special works. Especial praise may be given to the sections on treatment, which display that most excellent but rare virtue of common sense. Such a volume should be mastered by every senior student before examination and there are few, if any, better, than this. It further reduces to a practical form all that is needed for the busy practitioner to bring himself up to date as regards recent advances.

Society Reports.

AMERICAN ASSOCIATION FOR THORACIC SURGERY.

Third Annual Meeting, Held in New Orleans, La., May 1, 1920.

DR. RUDOLPH MATAS OF NEW ORLEANS IN THE CHAIR.

(Concluded from page 632.)

V. Lung and Bronchi.—1. Preliminary Report on Changes of Volume Induced by Alterations of Intrapleural Pressure.—Dr. EVARTS A. GRAHAM of St. Louis, Mo., read this paper by invitation.

2. The Importance of Both Sympathetic Superior Cervical Ganglia to the Maintenance of Life, and Their Possible Relations to Respiratory Diseases.—Dr. SAMUEL J. MELTZER of New York presented this paper. The superior cervical ganglion was known to control the vasoconstrictors of the ears, the vasodilators of the mucous membrane of the mouth, nose, conjunctiva, etc., the width of the pupil, and the pilomotor. Langley, by using his nicotine method, established that, except for the iris, the nerve fibers which controlled the above-mentioned phenomena originated in nerve cells within the ganglion. Meltzer discovered about eighteen years ago that instillation of adrenalin in the conjunctival sacs, which exerted no effect upon the pupil in normal individuals, caused a wide and long-lasting dilatation of the pupil on the side in which the superior cervical ganglion was removed. Simple section of the cervical sympathetic did not carry with it such consequences. The instillation began to exert this effect only twenty-four hours after the removal of the ganglion in rabbits and forty-eight hours after the removal of the ganglion in cats and in dogs. While all these effects of the ganglia were interesting from a physiological point of view, they in no way affected the life of the animal. In a long series of experiments carried on in the course of the last six months, the writer found that the removal of both superior ganglia in rabbits led invariably to the death of the animal. The death occurred mostly within two or three days after the removal. In a few instances the animals survived the operation six or eight days. The removal of one ganglion or the removal of parts of both ganglia did not lead to fatal results. Two rabbits survived the apparent successful removal of both ganglia. But by using the adrenalin test—that is, by instillation of adrenalin into both conjunctival sacs—it was discovered that one ganglion was not completely removed. The autopsy of the animals dying after the removal of both ganglia revealed the presence of extensive pulmonary lesions, which consisted in lobular pneumonia of both upper lobes, containing sometimes smaller or larger caseous abscesses, and the presence of pulmonary edema, especially in the enlarged lower lobes. The pneumonic lesions were the more extensive the later the animal died after the operation. In all cases the esophagus was found to be empty. The site of the operation was found to be uninfected. Extensive experimentation proved conclusively that the pulmonary lesions were not due to injuries of both vagi. Stimulations of the central end of one vagus after the removal of both ganglia had shown the different nerve fibers in the vagus which affect respiration, deglutition, and blood pressure were unimpaired. Simple exposure of the ganglia and intense manipulations of the neighboring vagi and the surrounding tissues without the removal of the ganglia never had any deleterious effect upon the animal. Cutting of both vagi in the neck caused the death of the animal within twenty-four hours with a characteristic aspiration pneumonia, while the esophagus was filled with food from the stomach. There was no doubt that the death of the animals was due to the removal of the ganglia, and not to any incidental effects. In a few experiments both superior cervical ganglia were torn away from their cephalic connections, but left *in situ* in connection with the sympathetic nerve, and, in addition, two ganglia which were removed from another rabbit were placed deep in the wound. These rabbits had so far survived this procedure. This

fact suggested that the superior cervical ganglia might possess an internal secretion. The importance of these results was obvious; but no theoretical discussion would be offered at this time. More actual experimental work would have to be done. But the writer wished to call attention to two practical points. The location of the superior cervical ganglia in close proximity to the pharynx and tonsils suggested the possibility of their becoming affected in infections of the tonsils and the pharynx, which might at times lead to affections of the lungs. It might possibly explain the occurrence of pneumonia after a comparatively unimportant affection of the upper respiratory cavities. Furthermore, in autopsies on patients dying from pulmonary diseases, the superior cervical ganglia ought to be examined as a routine matter. Another point was the introduction of the adrenalin test in diagnosis. In various diseases of the neck (thyroid, submaxillary glands, etc.) and the lungs, two or three drops of adrenalin could be instilled in both conjunctival sacs. In the course of time this procedure might develop into a useful diagnostic method. In the experimental work the adrenalin test proved to be a most satisfactory method.

3. The Treatment of Bronchial Fistula.—Dr. CARL EGGERS of New York read this paper. Bronchial fistulae were classified etiologically, he said, into those due to (a) Intrapulmonary suppuration; (b) external violence. Anatomically, they were divided into (a) bronchopleural fistulae; (b) bronchocutaneous fistulae. A short description was given of the different types, their diagnosis and importance. The treatment of bronchopleural and bronchocutaneous fistulae was then described somewhat in detail, calling attention to the importance of not attempting to close a fistula as long as it served as a safety valve for intrapleural suppuration. The reasons for the persistence of a fistula were explained. Then followed detailed case reports of six bronchocutaneous fistulae successfully operated upon during the last year. At the end the experience gained from these cases was summarized in the following conclusions: (1) Bronchopleural fistulae usually closed spontaneously. (2) In the few cases in which a fistula was responsible for the persistence of a chronic empyema, treatment favoring the obliteration of that cavity would result in a closure of the bronchus. (3) Bronchocutaneous fistulae must be carefully studied and their etiology and the present condition of the lung taken into consideration. (4) As long as the fistula acted as a safety valve for intrapulmonary suppuration it must not be interfered with. (5) Mobilization of the lung and fistula, allowing it to recede from its fixed position, was the most important factor in bringing about closure. (6) Muscle flaps were very valuable to cover the bronchial sinus after the necessary preparation had taken place. They aided in the closure and obviated deformity. (7) Canterization of the fistula should always be done very lightly, simply to destroy the epithelium, never so deep as to produce a slough. (8) In case the wound was clean, suture of the bronchus should be done. (9) In cases due to lung abscess, in which it was feared that closure of the bronchus might result in damming back of secretions with the danger of pneumonia, the bronchus should not be sutured, but a muscle flap simply laid over it, placing a drainage tube at some distance to act as a safety valve. (10) Whenever possible, the operation should be done under local anesthesia.

Dr. GRAHAM, by invitation, said he had been very much interested in Dr. Eggers' article, and he thought he undoubtedly hit the nail on the head. He had some experience in bronchial fistula and had found a method of some value which he thought was originally proposed by Dr. Meyer, namely, treating the bronchial stump like an appendix stump, inverting it into the substance of the lung and closing it after suturing the lung over it. Dr. Graham had a young woman who had an Estlander-Schede operation two years before with a permanent fistula connecting with a bronchus. She had several operations for the purpose of closing this fistula, but all were unsuccessful. The speaker performed a radical operation by turning up the skin flaps and dissecting out the tract for six inches into the upper lobe; he then located the tract, carbolized it, inverted it into the lung, and pushed the lung over the inverted portion; prompt healing occurred which had remained permanent for six weeks.

Dr. JAMES F. MITCHELL of Washington, D. C., said he had a great deal of experience with the smaller fistulae in their early work on the Empyema Commission, and they found, as Dr. Eggers had said, most of these fistulae would close themselves if left alone, and they did not contraindicate the use of the Dakin treatment. They found in several camps that the Dakin treatment had not been carried out thoroughly, and in many instances the excuse was that the patient had a communication with a bronchus and the consequent coughing caused its discontinuance. Dr. Eggers had emphasized the fact that the treatment could be continued, in spite of this fact, by changing the position of the patient or estimating carefully the amount of solution to be given each day. On the whole, then, he thought it was important not to attempt to operate on these cases too early; not until the condition was well established. It was the general rule in all complications of empyema. In the treatment of chronic empyemas or persisting cavities he thought there was too much consideration given to obliterating the cavity, instead of finding the cause of the cavity, sterilizing it, and leaving it alone. In the actual treatment of a fistula demanding operation the various methods had all been tried and found satisfactory. In some cases all that was necessary was to get an exposure of the mouth of the fistula, cauterize it, and, with or without suture, leave a safety valve so that the fistula would close.

Dr. PARHAM said that he tried very thoroughly in the case presented to use the Carrel-Dakin treatment and also dichlorimine-T, but the fluid in each instance would go up even into the patient's mouth. Even bismuth paste had to be abandoned, so that finally he had to content himself with putting in a tube the size of his index finger. After a year this opening had decreased in size, but the discharge continued and the bronchial fistula still communicated with the cavity.

Dr. HEDBLOM stated that he had found a skin flap method advocated by Beck good in some cases, the end results having been satisfactory. He thought the muscle flap method would in some cases involve a less extensive operation, and he intended to try it when a suitable case presented itself.

VI. Diaphragm.—1. Thoracoabdominal Injuries: Some Technical Procedures Developed by the War.—Dr. CHARLES GORDON HEYD of New York read this paper. The lethal factor within the first twenty-four hours in the thoracoabdominal type of wound was invariably shock or hemorrhage. In the type of case in which the abdominal lesion predominated there was, in addition to the peritoneal penetration, the visceral penetration with hemorrhage from liver, spleen, kidney, and mesentery, and the effusion of intestinal contents from the intestinal canal.

Anatomical Classification of Thoracoabdominal Injuries.—Thoracoabdominal injuries might be classified anatomically into six types. (1) The perforating wound through the costophrenic sinus with minimum degree of damage to diaphragm and which was characterized usually by slight, if any, visceral lesion. (2) Penetrating wound with orifice of entry high on the thorax, perforating the lung and penetrating the diaphragm with moderate or severe visceral injury. (3) A wound low down in the axillary line, usually in the seventh, eighth or ninth intercostal space, with injury to the liver, spleen, and stomach, with gross hemorrhage into the abdomen, and rarely perforation of the colon or small intestine, and in which the entire picture was dominated by the abdominal injury. (4) A wound low down in the axillary space with considerable loss of lateral chest wall and diaphragm, resulting in herniation or prolapse of the omentum and abdominal viscera into the thoracic cavity or externally. (5) A wound in the lumbar region with injury to the kidney and associated with injury to diaphragm and abdominal viscera. (6) Tangential wounds of the chest and abdominal wall with a concussion hemithorax and suspected chest and abdominal injury, but which upon operation proved to be superficial and without injury to either thoracic or abdominal viscera.

Visceral Injuries.—Liver, spleen and stomach.—When the liver was injured three types of hepatic wounds were observed: (1) The tangential wound through liver substance, trench-like in character and

usually with the hemorrhage arrested at the time of operation. (2) A secon with a complete clear-cut tunnel through liver substance and rarely with radiating fissures. (3) Fragmentation or pulpaefaction of a lobe or portion of the liver. The initial hemorrhage from liver injuries was severe, but regardless of the type of injury it had invariably stopped at the time of operation, except when the injury was in the nature of fragmentation where the hemorrhage was continuous in type and uniformly fatal. The operative approach varied with the type of injury and its location. The mechanical factors involved were in brief: (a) Injuries to diaphragm only—usually in costophrenic sinus. (b) Injuries involving penetration of diaphragm with damage to subjacent viscera and with or without gross loss of diaphragm substance. The repair of injuries to the diaphragm was immediately carried out or the diaphragmatic injury was enlarged so as to deal with intra-abdominal complications. There were obviously well-defined limits to the amount of work that could be performed upon the viscera of the upper abdomen, for with reduction of herniated viscera and repair of injuries to the liver, spleen, portions of the cardiac end of the stomach, and occasionally the colon, very little further operative manipulation could be carried out. For injuries lower down in the abdomen it was necessary to supplement the thoracic technique with a laparotomy to deal specifically with the abdominal condition. The suturing of the diaphragm was a matter of comparative simplicity and after the first suture was tied it was utilized as a traction suture and the remaining portion of the diaphragm was readily sutured with a lock-stitch No. 2 chromic catgut. It would seem that these experiences in thoracoabdominal injuries pointed the way to a better technical consideration of diaphragmatic hernia, for with positive pulmonary anesthesia and distention of the lung it should not be dangerous to do a major thoracotomy in the seventh or eighth interspace and approach the reduction of a diaphragmatic hernia from within the chest and by suture of the diaphragmatic hiatus from the thoracic side accomplish a much better technical result. Lesions of the liver, superior cardiac portion of the stomach and some spleen lesions might offer a wider application for transthoracic laparotomy with better results than were now obtained by any classical methods of approach through the abdomen. The treatment of heart wounds through a transpleural exposure and by means of an intercostal incision under differential pressure anesthesia offered a quick, technical exposure with ample room and obviated the dangers of pneumothorax and seemed to indicate a better technique than any type of extrapleural operation.

Dr. LEWALD said he was interested to know in the case where the projectile was missed in the pancreas whether or not there was a satisfactory explanation for this. The mere fact of having located one projectile should not have led the roentgenologist to feel that he had no further duty, or did one shadow overlap the other, and was the case examined only in one direction? Of course such mistakes were known to happen.

Dr. PARHAM stated that Dr. Heyd spoke of a hemithorax by concussion, and he was interested because he had recently a very interesting case of a young boy who was struck by an automobile, struck on the left side of the chest and knocked down with great violence; when he was picked up by the gentlemen who had run over him, he was not unconscious; he was brought to the Infirmary a few blocks away and the speaker saw him within an hour. He was able to make out a pneumothorax with evident hemorrhage into the cavity. He examined the patient very carefully but could find no injury to the ribs. The patient was in a state of great shock and he could do nothing but carry out a waiting treatment. He lived 26 hours, conscious to the very last, but with his breathing very much impeded, and the question was whether or not they should explore his thorax. There was evident hemorrhage with possibly a hemithorax. He called in the best internists and asked them to answer the question whether to relieve the impaired breathing by withdrawing the blood and they decided against this procedure. He was told later by a medical man who was a friend of the child's family that on autopsy they withdrew from the thorax 28 ounces, and from the stomach 14 ounces of blood. Where did the blood come from which he vomited be-

fore death and that which was found in the stomach after death? Those in consultation were of the opinion that this blood came up from the lungs and was swallowed. The speaker sent in the death certificate as rupture of the lung with hemorrhage and pneumothorax.

Dr. MITCHELL stated he had a case somewhat similar to that mentioned by Dr. Farham which he would like to report. A young girl was run over by an automobile truck which passed directly over her chest. She was brought into the hospital in a state of shock. It was later discovered that seven of her ribs were fractured on the left side. She developed marked cyanosis, great difficulty in breathing, and he too called in a medical man who advised against aspiration saying there was in his opinion no blood and that it was best to leave the chest alone. The speaker disregarded his advice however, and aspirated two quarts of fluid blood and this girl made a splendid recovery and had no further trouble.

Dr. EGGERS said Dr. Heyd made a statement which he did not entirely understand. He said he had learned to disregard acute pneumothorax. Did he mean closed or open pneumothorax? There was a vast difference in the cases. In speaking of pneumothorax, one must bear in mind whether one referred to an open pneumothorax, existing for a short period or a continuous pneumothorax. They must all admit that it was possible to operate in a pleural cavity without positive pressure if one closed the thorax after; if one left it open it was a different matter. An acute open pneumothorax was a very dangerous condition.

Dr. MATAS remarked that the question of technique was always important in dealing with these cases. There was a question in his mind brought up by a case occurring some years ago of laceration with fracture of the ribs, tearing of the diaphragm with protrusion of the spleen, part of the colon, and the stomach. In enlarging this incision over the crushed area he did it transversely; it was very easy and simple to put back the whole mass and suture the diaphragm in the manner described. He believed the point in dealing with cases where there was no crush was whether it was best to do an intercostal incision with wide horizontal retraction or a vertical incision with wide lateral retraction and if necessary supplementary section of the ribs. In his opinion nothing could exceed the advantage of the intercostal incision: once exposed there was no doubt about the superiority of the upper route.

Dr. GEORGE P. MULLER of Philadelphia, Pa., said, by invitation, that he had operated on two cases of combined abdominothoracic injury and found no difficulty in getting good exposure from below: the chief difficulty he had was caused by the diaphragm rising out of reach on attempting to pass the needle for the introduction of the sutures. He learned in splenic operations to cut transversely, the subsequent repair of the muscle being just as good as with straight incisions, and in that way one could get well up under the costal arch. In one case of stab wound with a three-inch incision into the diaphragm it was possible, after getting one stitch in, to steady the diaphragm until he had sewed the rest. Gunshots in civil life varied from those in military practice. Lead bullets would deflect themselves from the ribs as they entered the thorax as a rule or ricochet under the scapula. One did not see the "stove-in" chest or the extensive comminution of ribs. The methods used in military practice, however, could be applied to civil injuries. In one case he was able to extract the bullet from the lung with perfect convalescence, following the technique of Duval; in another stab case a similar result was obtained after thoracotomy.

Dr. ANGELO L. SORESI of New York City, by invitation, said the points that he would like to bring forward were that organs that had passed from the abdominal to the thoracic cavity and were adherent either to the diaphragm or to the thoracic organs or to both, could be well exposed and freed through the abdomen provided the patient's head was raised in order to expose well the diaphragm and the hernial opening in the diaphragm was widened enough to allow a free vision of all the organs concerned. Then the work was very easy and the patient was saved from the additional shock and other complications caused by the extra incision in the thoracic wall. One must not be afraid to make a

long incision in the diaphragm because it could be easily and well repaired by using the special suture which he illustrated, and which he described in his paper on "Diaphragmatic hernia," published in the *Annals of Surgery*, March, 1919. The ends of the catgut were tied on the abdominal side of the diaphragm. In one of his patients he made an incision about four centimeters long, and freed the stomach very easily without any need of opening the pleura. The patients were discharged cured after a few days, except one whom he kept in the hospital about a month because he wanted to show him before a surgical society.

Dr. HEYD, in closing, said concussion hemothorax was not uncommon. He recalled two men who entered the hospital with acute hemothorax and without any evidence of injury to the chest other than bruising of the chest wall. These men were quite close to a shell burst. In the front line hospitals all surgery on skull and chest carried with it the operative rule "close the cavity." The technical objective in all such surgery during the first eight hours—the period of contamination—consisted in debridement, removal of bone fragments, regularization of bone ends, excision of all traumatized tissue and hermetical closure of the pleural cavity. So far as lacerations to the diaphragm were concerned it was their belief that the rational procedure was a major thoracotomy in the seventh or eighth intercostal space. If herniation or prolapse was found the abdominal viscera could be replaced through the thoracic wound easier than through a laparotomy wound, as in the former one did not contend with the negative pressure of the thoracic cavity. Shell fragments were the chief source of danger and not bullets. A bullet could, however, produce a terrific degree of damage if it hit a bone and carried bone fragments before it. So far as suturing of the diaphragm was concerned they were interested only with a good anatomical closure. This could be achieved by a lock-stitch of No. 2 chromic catgut. It was found that there was a point beyond which the injured man could not survive operative procedures and the surgery involved elimination of classical procedures which experience demonstrated as being superfluous. Decision had to be made quickly and technical procedures carried out expeditiously and with a minimum of manipulation.

VIII. Posterior Mediastinum.—1. Suppuration in the Posterior Mediastinum: Its Surgical Treatment, with Report of a Case.—Dr. WILLIAM LERCHE of St. Paul, Minn., read this paper. Including the case of the writer, there were only ten cases of suppuration of the posterior mediastinum reported that had been drained by the cervical route. The patient, a woman aged fifty years, had for six years been troubled with a peculiar brassy cough. At times she had severe paroxysms of this cough, accompanied by dysphagia. A deep seated abscess of the neck finally developed and extended into the posterior mediastinum, which was drained through an incision on the neck. The patient made a good recovery and had no return of the cough or dysphagia during the thirteen years elapsed since the operation, which was performed in 1907. In most of the cases reported, the mediastinal suppuration was due to accidental perforation of the esophagus by a foreign body, or to instrumentation. In the case of the writer's, the lymph nodes of the recurrent chain were in all probability the original seat of infection; being chronically inflamed, they caused the symptoms by irritation of the recurrent laryngeal nerve, and finally breaking down formed the abscess. In order to demonstrate the probable route by which the suppuration of the neck extended into the mediastinum, the writer injected a barium-buttermilk mixture into fresh cadavers and radiographed them. Observations were also made of the peristaltic wave of the esophagus through an endoscopic tube introduced through the neck wound into the mediastinum. Most cases in which the mediastinal suppuration originated in the neck could be drained by the cervical route. In cases where drainage by the latter route was not sufficient, a dorsal mediastinotomy might have to be added later.

Dr. MATAS said he would like to relate an experience which occurred in his practice more than 15 years ago, and which he remembered very vividly as it gave him great concern at the time. The patient, a boy of seven years, had swallowed lye and the usual impermeable

stricture of the esophagus had followed. He was in a starved, marasmic condition. He regurgitated even water and was dehydrated, presenting the appearance of a mummy with the skeleton outlined everywhere through the thin skin. All they could do was a gastrostomy followed by a retrograde dilatation on the Abbe plan. They fed him and he responded very quickly; he gained strength and flesh progressively and he could be nourished cautiously through the mouth. After that they used dilating bougies which he learned to pass with little assistance. One day, however, while passing the bougie, he felt an acute retrosternal pain. They watched him closely, and a violent chill, followed by high fever, and marked signs of shock and prostration told that the esophagus had been ruptured and that the esophageal contents had escaped into the mediastinum. His temperature continued high and he was in a desperately septic state for five days. Dr. Matas thought he would die from an acute septic mediastinitis, as, in such cases, the dilated esophageal pouch above the stricture was so foul that the escape of even a small part of its contents was sufficient to set fire to the peri-esophageal tissues and cause the most virulent putrid phlegmon in the mediastinum. While he was debating in his mind whether to do an anterior or posterior mediastinotomy for drainage, he noticed a progressive edema over the root of the neck and upper sternum. This spread rapidly with very little redness at first, but it soon became quite tender over the suprasternal notch, showing that the suppuration was extending upwards and forwards. With this indication pointing the way, he made a deep dissection of the neck, dividing the sternoclavicular attachments of the left sternomastoid muscle, and after displacing the vessels worked his way down to the trachea and esophagus, very slowly feeling his way behind the sternum until he could feel the pulsation of the aorta. The retrosternal tissues were very edematous and while he was probing and feeling his way with a long blunt pointed vaginal forceps, a sudden gush of putrid pus and gas escaped, which announced that the abscess had been tapped. After this the problem became one of drainage. They had then, no handy suction apparatus for continuous aspiration by electric motor, as at present. He could then only favor drainage by position and gravity. The boy was put on a cot in an exaggerated Trendelenburg position, with a drainage tube in the neck leading to the retrosternal abscess. In this position he was kept for over a week, when the pus diminished sufficiently to allow him to substitute a gauze drain for the rubber tube which was lying in dangerous proximity to the great vessels, suggesting the possibility of an erosion hemorrhage. The suppuration ceased altogether and the abscess healed, but they never ventured to resort to dilatation *per os* after that accident. The boy was fed regularly through the gastric opening. He is now a grown man and, until the last two years, he was seen often. He was employed in a factory, but he made his living chiefly by exhibiting himself as a "freak" and showing how comfortably he could live through a stomach tube. He frequented bar rooms and often astonished the crowds with the amount of beer that he could dispose of. He had disappeared in the last two years and the speaker feared his bibulous habits might be largely responsible for his disappearance. If this was true, it was a pity, as with the superior methods of exploration and with the help of radiology, it was more than probable that the permeability of the esophageal tract could have been restored. The speaker had seen two cases of perforation of the esophagus in connection with esophageal stricture of malignant character. These patients died in a short time; he did not think any operation was applicable because they are not, as a rule, fit for interference.

Dr. GREEN said he thought that this was a most timely paper. He had quite a number of esophagus cases, having done some somewhat the same kind of work in New York as Dr. Lerche was doing in St. Paul. He could not say he had not been unlucky for he had had perforation of the esophagus, and yet he had it in but one case, a carcinomatous esophagus where the growth had almost eaten through into the trachea. It occurred while he was sharing the responsibility with another man, the operation not being entirely under his con-

trol. In that case they had a perforation while using the other surgeon's bougie which "squashed" the carcinoma into the trachea from pressure. The patient died in twenty-four hours. Also when Dr. Janeway and he were first doing this work they were called to the Roosevelt Hospital to see a case with a cicatrix of the esophagus following a burn by lye, which had been manipulated by another physician some hours before they saw the patient. This case had a mediastinitis, was not drained and did not get well. The speaker had a patient, a woman, whom he had followed for a number of years: she took lye by accident when she was a young girl of five or six years, and Dr. E. Farquhar Curtis did a gastrostomy, dilating the esophagus by the string method of Dr. Abbe. She did pretty well for a while but finally her stricture closed and also her stomach wound. Then Dr. Green had to operate all over again. That was some 15 or 16 years after the first operation. She would sometimes go for periods of six months, and then return for bougie treatment, and sometimes had a cough after this treatment. He was frequently fearful of a perforation into the mediastinum. During the last year at one of these treatments he could not get the bougie into the stomach: he could not bring himself to force the bougie down: after quite a little manipulation, however, she could swallow better, so he was put to it to determine whether or not the bougie passed into the stomach. He therefore designed a fairly stiff bougie with an electric light in the end, and on the passage of this instrument he could tell when it had passed into the stomach. By darkening the room and having the patient lean well forward, the light showed up very satisfactorily in the epigastrium right through the abdominal wall.

Dr. HEDBLUM said he had one case of abscess of the mediastinum in a child of five years. The symptoms were dyspnea and cyanosis. The x-ray showed a mediastinal shadow which was taken to be due to an enlarged thymus. Because of the urgency of the case an exploration was deemed advisable. After a preliminary tracheotomy, the upper sternum was split and edges retracted. An abscess was opened into, and several drams of pus evacuated. The dyspnea was partly relieved, but he died rather suddenly after awakening from the anesthesia, apparently from asphyxia and acute dilatation of the heart. Necropsy was not allowed.

Dr. MULLER, by invitation, stated he had recently had a case of suppurative mediastinitis in a patient with an unusual history. A girl 25 years old; ten years previously had suppurating glands above the clavicle, presumably tuberculous: within two years she developed pulmonary tuberculosis, was treated in a sanatorium, seemed much improved and came home, although she still had tubercle bacilli in her sputum. She then developed a swelling just above and to the left of the sternum. This increased in size during the period of a month causing intense pain, which seemed to aggravate her pulmonary condition. Under local anesthesia an incision was made and he found what looked like a cyst 8 to 10 cm. in diameter, the walls of which were closely applied to the great vessels and trachea. He did not know what it was unless a cyst of the thyroid or a cystic hygroma of the neck, but packed it with dichloran-T gauze, and introduced rubber drainage. The discharge then became purulent, he was unable to state whether or not the fluid was tuberculous as it was lost before examination. She went with a small drainage tube for seven or eight months and whenever the tube was removed she developed pain and fever. Finally he decided to inject the sinus with bismuth paste. When the bismuth was injected she gave a slight cough and raised some bismuth so that they did not see as much in the x-ray as they had put in. There was a rise of temperature, and the x-ray showed that the bismuth had extended down to the mediastinum. She died five or six weeks later, after an increase in her pulmonary symptoms. In the mediastinum were found a large mass of dense glands, soft in the center and perforating into the trachea. The cavity communicated by the sinus with the neck.

2. Roentgen Findings in Three Cases of High Non-malignant Esophageal Obstruction.—Dr. LEON T. LEWALD of New York City read this paper illustrated with lantern slides. In contradistinction to the usual

malignant obstructions encountered in the esophagus, the following three cases were of unusual interest because of their non-malignant nature, although two of the cases were within the cancer age. The value of an early roentgen examination in every case of suspected esophageal lesion could not be too strongly urged.

CASE I.—Bulbar lesion producing esophageal paralysis ending in recovery. C. S., female, age 72. Three years previous to the present illness she had a cerebral hemorrhage. At that time there was a complete paralysis of the right arm and partial paralysis of the right leg together with aphasia. The blood pressure was 235. After a period of treatment the blood pressure was reduced and the symptoms of hemorrhage disappeared. Concerning her present illness the patient stated that on waking in the morning she noticed that her mouth was filled with saliva and there was a choking sensation. She found that she could not swallow anything. The larynx on examination appeared normal but when food was taken it remained in the upper part of the esophagus overflowing into the larynx. It was impossible to pass a small stomach tube. The patient was x-rayed at St. Luke's Hospital and the following report rendered, "There was a definite obstruction in the esophagus right at the origin, so that some of the opaque mixture which was given began to pass over into the trachea and down the respiratory tract into the bronchi, especially on the left side. The roentgen findings indicated a paralysis of the esophagus rather than an obstructive lesion due to new growth." The case might be explained on the basis of a spastic paralysis where the normal peristaltic wave of relaxation, which usually preceded the contraction wave, had been inhibited. The patient was fed through a Jutte duodenal tube for two weeks. It was then found that she could take small amounts of dry foods but that there was still great difficulty with liquids. She continued to improve, however, and after a time completely recovered. It would seem most reasonable that the condition was produced by the occlusion of a small vessel in some part of the pons. There was no evidence of paralysis of the laryngeal muscles, vocal cords or soft palate.

CASE II.—Partial esophageal obstruction due to spasm following an operation on the thyroid. E. B., female, age 42. Five months before coming under their observation a partial thyroidectomy had been performed. For the past four weeks there has been a feeling of oppression in the upper part of the chest and a sense of constriction in the neck. The patient thought that there was delay in swallowing. X-ray examination gave the following observations. Chest: there was no evidence of substernal goiter observed; the heart and aorta were of average size and the lungs showed no shadows indicative of infiltration; the thymus did not appear to be enlarged. Esophagus: There was delay at the entrance of the esophagus. It was difficult to tell whether this was due to spasmodic contraction or pressure, but in view of the tendency to disappear between examinations it was probably of spasmodic nature.

CASE III.—Retropharyngeal and periesophageal cellulitis complicating tonsillitis and causing esophageal obstruction. J. P., male, age 20. One week before admission to the hospital the present illness began with a sore throat, chilliness and general malaise. On admission the tonsils were noted to be markedly swollen and the crypts filled with cheesy material. The cervical glands were enlarged and tender and there was a bulging mass below the angle of the left jaw, apparently a very much enlarged gland. Some tenderness over both lobes of the thyroid was also noted. The patient was examined with the fluoroscope with the following observations. There was marked swelling of the tissue of the neck. The peribronchial shadows were slightly increased, the infiltration extending down to the second interspace anteriorly. There was partial obstruction of the esophagus opposite the entrance of the larynx, apparently due to pressure. Three days later the patient was re-examined under the fluoroscope with the following findings. There was practically complete obstruction of the esophagus at the uppermost portion. The possibility of the cause being a retropharyngeal abscess, compressing the esophagus, should be given most careful consideration. The obstruction

was so complete that it would necessitate feeding the patient through a tube or some other procedure. Radiographs of the sinuses at that time showed cloudiness of the right maxillary sinus. Five days later physical examination showed dullness at both apices of the lungs and coarse and fine rales at the right apex. A radiograph of the chest was made on the day following and it was noted that there was a distinct opacity on the right side of the chest extending down as far as the first rib anteriorly. The exact nature of the lesion was not evident. Four days later x-ray examination showed that the area of density on the right side of the chest above the first rib had largely disappeared.

Dr. GREEN remarked that Dr. LeWald had had large opportunity to watch the esophageal cases and had been of great aid to him in making the diagnosis in these cases. Of the case he mentioned which the speaker had an opportunity of seeing with him he would like to give the chronology on a little more accurate scale. This patient came into the hospital during his absence and it was considered he had an obstruction of the esophagus. A gastrostomy was done at once. When Dr. Green returned he esophagoscoped him and Dr. LeWald took a roentgenogram. (He always tried to have the patients examined by the roentgen ray first.) He found the esophagus was large and somewhat atrophic, little wrinkles running transversely all the way to the stomach, with no obstruction. The man kept getting a little worse, so far as his speech and swallowing were concerned and he began to suspect bulbar palsy. The diagnosis was later fully established and he was removed to the City Hospital. There the speaker had Dr. E. L. Hunt see him, and he confirmed the neurological diagnosis. The patient died. He saw another case with Dr. Mathews. This man could not swallow. He examined his throat with his finger and came immediately upon a retropharyngeal abscess. This was opened and drained. This man recovered.

Dr. GRAHAM, by invitation, said it had happened that during the last few months he had an unusually large number of carcinomas of the esophagus admitted on his service. Many of these were in a state of most extreme inanition. He could not help but feel from his personal experience that gastrostomy should not be an emergency operation. One would avoid many errors of diagnosis if one got out of this idea. These people were suffering from dehydration rather than from starvation. One could not only make them more comfortable and in better shape for operation if one got up their fluids temporarily, but that would also allow of a more correct diagnosis of the esophageal condition, and prevent in some cases the necessity of a gastrostomy later on. They had followed out this procedure, not merely giving them salt solution, but giving them subcutaneously glucose solution, 3 to 5 per cent. also by rectum. This glucose solution subcutaneously would not produce necrosis, it was sometimes a little painful, but it would have a marked effect in improving the general condition of the patient.

Dr. LEWALD, in closing, said he wished to add that they had seen three cases of cardiospasm in very young subjects. Also, at the Mayo Clinic two months ago, Dr. Moore told him they had a cardiospasm in a child about ten years of age. These early cases he thought were rather unique and tended to give the impression that it might occur much earlier than heretofore believed.

3. New Instruments for Esophageal Surgery. (a) Further Report on the Sausage-Skin Method for the Early Diagnosis of Cancer of the Esophagus. (b) Treatment of Cicatricial Stricture.—Dr. ARMISTEAD C. CRUMP of New York City presented these instruments and read a short paper illustrated by lantern slides.

Dr. LEWALD said he would like to know whether Dr. Crump had encountered any syphilitic lesions of the esophagus, inasmuch as they had seen a number of cases of syphilis of the stomach. One case he showed disclosed rapid passage of material from the stomach together with a very small stomach, which they had considered usually associated with syphilitic lesions. He asked whether he had had any evidence along that line.

Dr. CRUMP, in closing, said that during the series of esophageal cases which he has had during the last eight years of which there had been about fifty, sev-

eral had syphilitic histories. Some of these malignant cases had failed of diagnosis by other methods. One case he thought of as primary specific in character later proved to be epithelioma, as shown by a specimen. This man had a 4 plus Wassermann but derived no relief from specific treatment. Regarding the case mentioned by Dr. LeWald as bearing a strong resemblance to a specific process in that the patient had no specific history and the Wassermann was negative. At operation, the whole fundus was found involved, spleen adherent to stomach but no involvement of the mesenteric glands. A partial gastrectomy and a splenectomy were done after having previously separated the lower esophagus by means of a thoracotomy. The patient lived only a few hours after the operation. Microscopical examination proved the process to be a carcinomatous one. The autopsy found no extension outside of the original focus.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, Held February 23, 1921.

THE PRESIDENT, DR. GEORGE MORRIS PIERSON, IN THE CHAIR.

Nature and Treatment of Chronic Arthritis.—Dr. RALPH PEMBERTON said that chronic arthritis was one of the oldest diseases, long antedating civilization. During the war the number of cases had been very large—about 40,000 cases in an army the size of that of the United States in 1918. Dr. Pemberton said he was fortunate in having been stationed at General Hospital No. 9, where he was enabled to study the largest number of cases of arthritis ever examined under controlled conditions. Much that he had to say was based on the experience thus gained with the help of several collaborators. The more we learned of this disease the more we realized that most types were probably referable to the same pathology; perhaps the great majority were referable to the same underlying cause. He studied 400 cases among soldiers and found that exposure played a very large rôle in inducing their attacks. The rôle of infectious foci in teeth, tonsils, etc., to-day was widely accepted and true and he had been much interested to find to what degree exposure was a precipitating factor. The next factor was dysentery, which held a rôle comparable to that played by focal infection. The knee was the joint most frequently involved. That tallied with experience in civil life. In soldiers it had been interesting to see that drilling had not produced any greater incidence of the disease in that joint. The ankle and shoulder followed in comparable numbers. The surgical foci were chiefly in the teeth and the tonsils. The genitourinary tract played a very small rôle in these cases and lues was a negligible factor as a causative element. The basal metabolism in this series of some thirty arthritides fell below the normal range in 20 per cent. As to the nitrogen of the blood, despite much that had been thought and alleged in regard to arthritis there did not seem any clear reason for believing that there was any serious disturbance of the nitrogenous elements. Withholding red meats, for example, seemed to have no specific support. As to the calcium of the blood it was of interest to note that no disturbance could be detected in these individuals at the fasting level, although nothing was more clear than that calcium was disturbed in arthritis, because we knew the bones became rarefied. A good deal of evidence on the part of modern investigators had indicated a definite relation between blood creatine and carbohydrate metabolism. In 50 per cent. of these arthritides there were high values for the blood creatine and some of these higher values of creatine fell to normal as the case progressed. There was no disturbance of the carbon-dioxide containing power as indicative of any systemic acidosis in this condition. The output of water and salt in normals and arthritides was studied and it seemed from the so-called nephritic test that there was apparently a little lag in the output of water and salt as compared to the normal, indicating that the kidney function was to a small degree involved. Dr. Pemberton believed personally this had much

more to do with the secondary results of the disease than the causative factors. He did not believe that the renal involvement played any rôle in the production of the disease. There was a good deal of evidence that there was some disturbance of carbohydrate metabolism in arthritis. It was interesting to note that the incidence of arthritis was greatest at the time when the metabolism went down physiologically. The age curve of metabolism was one which rose sharply in childhood and went down in later life. There was no question that the outstanding causes of arthritis in civil life were foci of infection, which, depending on the age of the individual, occurred chiefly in the teeth, tonsils, and, lastly, in the genitourinary tract. However, other agents might do the same thing—pneumonia and dysentery may play a definite rôle. Other causes which could produce arthritis were disturbances of the ductless glands. An undue food intake undoubtedly produced arthritis in those in whom the groundwork was laid. Finally, the large bowel might be a factor, as Lane had emphasized. The agents which improved arthritis were those which tended, apart from removing focal infection, to combat the tendency toward a lowered metabolism. The more the speaker saw of this disease the more he was impressed with the difficulty of analyzing correctly for focal infection. It was difficult to determine when focal infection was present and where it was, but it was equally hard to remove and there were some situations in the body from which focal infection probably could not be removed. Treatment of cases of arthritis based upon removal of focal infection was not complete merely with the removal of the infecting focus. These cases had more or less disturbance of the body chemistry. After taking out a pair of tonsils in a subject with arthritis we assumed too frequently that he would get well and ignored the fact that there had taken place a serious disturbance—in physiology which we could not entirely read. He might remain sick for several years. The agents which were beneficial in arthritis were those which tended to combat this condition of somewhat lowered metabolism. They were arsenic, probably potassium iodide, certainly thyroid extract when it could be used; the x-ray; radium, which had great difficulty of application; electricity; exercise, which was a perfectly definite means of raising metabolism; massage; nonspecific protein; heat and hydrotherapy, the last mentioned playing a very important and useful rôle in this disease.

Dr. J. CLAXTON GITTINGS said that the result of reducing the demand upon the body metabolism in patients that had been thoroughly studied and in whom all foci had been removed and all other theoretical causes had been eliminated was undoubted to his mind. In his talk with Dr. Pemberton, in attempting to determine what was the particular food material at fault and what line of treatment a man who knew comparatively little of metabolic processes could carry out, he was impressed with the fact that even Dr. Pemberton, with all his experience, was unable, without a great deal of study, to determine what was the best measure of deprivation for any individual and, as he had emphasized, this question of diet, although in the main it may be accepted as one of the most important measures in the relief of these patients, was certainly one which could not be attempted without knowledge of the tools, so to speak. Dr. Gittings said he had also been impressed with the figures of the effect of the removal of foci. The fact that so many of the patients developed their arthritis in the entire absence of foci and others recovered in the presence of foci showed that, although the agency of the focus was certainly long established, at the same time it was by no means the sole cause *per se* in a very definitely large class of cases.

Dr. NATHAN P. STAUFFER said that at first he was under the impression that cases of arthritis were all due to focal infection. As a nose and throat man he was wont to ascribe brilliant recoveries to operation, but Dr. Pemberton afterward convinced him by his work and by his patients that he had seen that it was due to many other causes than just focal infection, and he was quite sure that Dr. Pemberton had found one of the theories in his carbohydrate or intake theory. These patients were markedly improved by regulat-

ing their diet, even though they had focal infections present at the time, because many of the cases had gone on and not been operated on, due to the patient's unwillingness to be operated upon, and even those who had a focal infection removed had not been entirely well until they had carbohydrate tolerance established for them. He also believed that hydrotherapy was a great help as a therapeutic measure, and all had seen it probably in the ordinary cases of backache, which they all got.

Rheumatic Fever and Its Variants in Childhood and Adolescence.—Dr. DAVID RIESMAN said that rheumatism was not, like typhoid fever or diphtheria, a unit disease, manifesting itself in a more or less uniform manner. The rheumatic chain had a number of apparently dissimilar links, the connection of which with rheumatic fever was not easily established, although there was abundant evidence that such connection existed. The links referred to were chorea, tonsillitis, rheumatic polyarthritides, rheumatic carditis. The etiological factor in rheumatism had not been demonstrated. Perhaps we should have to look for a filterable, or ultramicroscopic, organism yet to be discovered. The greatest mortality from acute articular rheumatism was in the age period of from five to fifteen years. While in adults the disease spent itself chiefly upon the joints, in the child it had a much greater tendency to attack the heart; the joint involvement in the latter was often so slight as to be overlooked, yet the cardiac involvement might be severe. Tonsillitis was in the child a frequent precursor of rheumatism, while chorea was at times a sequel. Cardiac involvement might come within twenty-four hours of the beginning of the rheumatic attack and its discovery depended upon a careful routine study of the heart. The mitral lesions thus caused were capable of complete recovery, though the aortic lesions practically never recovered. Because of compression of the left lung by the pericardial exudate, physical signs of pneumonia in this lung might present themselves. The most characteristic skin lesion was the so-called rheumatic nodule, which histologically resembled the miliary nodule in the heart muscle. These were usually few, occasionally enormous in number, and were found chiefly about the elbows, backs of the wrists, near the ankles, and over the buttocks. Diagnosis offered a large field and there were many chances of error. When only one joint was involved great care must be exercised, as the trouble was in such cases apt to be due to osteomyelitis or gonorrhea. As to treatment, the salicylates, whether specific or not, held first place. The dose must be 90 to 150 grains in divided doses at short intervals during the first twenty-four hours. The choice of preparation was not very important; personally he preferred the sodium salicylate combined with a nearly equal amount of sodium bicarbonate. After the first twenty-four hours the dose might be lessened. If the case responded at all the fever and pain would subside in forty-eight hours. In some cases morphine must be given. The joints might be wrapped in cotton or local applications of lead water and laudanum, magnesium sulphate or oil of gaultheria made. A splint might be applied. Abundance of water, lemonade and orangeade should be given. The food should be in the form of milk or milk products, cereals and broth. Until the causative agent had been isolated the use of vaccines and serums was purely empirical. In rare instances the use of a stock vaccine had proved beneficial. If the tonsils were diseased they should be removed, but not, of course, during the attack.

Dr. J. P. CROZER GRIFFITH said that the frequent mildness of acute articular rheumatism in children who had passed the age of five years was to be particularly emphasized. Many of us made a mistake in being too ready to call a case rheumatism in a child under the age of five years, at which period of life it was distinctly rare. All statistics proved the same thing, and yet it had been Dr. Griffith's experience to see cases of scurvy in infants where the diagnosis of rheumatism had been blithely made by the physician who had had the patient in charge. Anyone who would bear in mind that infants did not get rheumatism would avoid this mistake. After the age of five years it was likely to show itself in a mild way until the

period of puberty and was therefore likely to be overlooked, consisting of vague aches of various sorts of which the patients had taken practically no notice at all. One of the most important indications of rheumatism was cardiac rheumatism. He believed thoroughly that the cardiac manifestation might be the first manifestation of all of the rheumatic condition, that it might occur without any rheumatic disease of any sort. Certainly it occurred after chorea without any condition which we knew. It was his firm conviction that the great majority of chorea cases rested upon a rheumatic basis and that 50 to 75 per cent. were in reality rheumatic. The subcutaneous nodules of which Dr. Riesman spoke, common as they were in England, though first described by a French writer, had been, in Dr. Griffith's experience, rare in this country. He agreed that purpura was not always to be called rheumatic, and questioned whether it was ever to be called a symptom of rheumatism, although it was true that joints were often involved. We should treat rheumatism and its complications in early life. He believed in the statistics, which he had read that mitral disease (mitral regurgitation) was probably present in every case of endocarditis in childhood. All the autopsies seemed to prove that aortic disease was frequently present too, not stenosis, but the regurgitant condition. In the treatment of rheumatism he gave salicylates quite faithfully. He did not know whether it was right to be so much of a nihilist, but, to tell the truth, except to relieve pain, whether they had any influence upon the disease he questioned very much.

Dr. A. BRUCE GILL said that the subject of arthritis, whether of disease in childhood or acute arthritis in adult life, was a large subject. He thought there was a close relation probably among all forms of arthritis, whether in infancy, child life or adult life. When we found that many of these cases were due to focal infections, apparently as the experience of all of us, then we jumped to the conclusion that the form of arthritis was an infection in the joint. That was the easiest thing to say, but so many investigators had shown that these joints were sterile; then we were obliged to take a step further back and say it was the presence of a toxin which was manufactured in some distant part of the body. Do we understand what that means? That was taking a step further back in the dark into an undiscovered country. Some of these cases were anaphylactic. Then came a distinct relation between the general metabolism of the body and arthritis. He thought we were free to say that we did not yet understand the direct relation between metabolic changes and the changes in the joint. He was not quite clear in his mind whether the metabolic changes could be ascribed to a concomitant condition or whether they occurred with arthritic changes, or whether there were other causes such as lowered resistance from injury or faulty posture which gave a lowered resistance in the joint, thus giving these metabolic changes an opportunity to have effect upon the joint structures. His hearers would be surprised if they knew how many cases came to the orthopedic clinics with acute osteomyelitis and tuberculosis, which had been treated by physicians for a considerable time as rheumatism. Differential diagnosis was important. Damage was done by failure of early diagnosis and failure of early treatment. Also, in connection with this condition of acute rheumatism, Dr. Gill believed that, if the joint was splinted, the pain would be allayed without the salicylates.

Dr. ROBERT G. TORREY said that the whole point in treating rheumatic fever was to prevent cardiac disease. Dr. Tyson had gone into this subject from statistics gathered from all sources and found those patients treated by salicylates showed a higher incidence of cardiac involvement than cases not so treated. That he did not think meant that salicylates should not be used, but it meant just this: that if we could allay the acute arthritis by giving salicylates, unless the patient were well under control, he would get up too soon. If the joints were under control, the heart would have a better chance of escaping damage. English statistics seemed to indicate that salicylates used early and in full doses certainly had a good influence in controlling, or rather modifying, the incidence of cardiac involvement.

Miscellany.

A NOTE ON THE HISTORY OF ARSENIC IN THERAPEUTICS.*

BY CHARLES GREENE CUMSTON, M.D.,

GENEVA, SWITZERLAND.

PRIVAT-DOCENT OF THE HISTORY OF MEDICINE AT THE UNIVERSITY OF GENEVA; A VICE-PRESIDENT OF THE HISTORICAL SECTION, ROYAL SOCIETY OF MEDICINE OF LONDON, ETC.

To what science more than to therapeutics can Ovid's melancholic remark be applied with more propriety:

*Tabida consumit ferrum, lapidemque vetustas,
Nullaque res majus tempore robur habet* (Ovid, letter viii)

and how few are the drugs employed by the fathers of medicine that have been able to resist the test of time.

Empiricism and tradition which composed the stock in trade of ancient therapeutics have gradually given place to both critical and experimental methods of a truly scientific character. We are no longer in the heroic age of medicine, an age when the apothecary's laboratory offered a singular likeness of the grotto of a Canidia or a witch of Macbeth, where it required hardly less courage to the poor wretch occupied in the preparation of innumerable remedies, than to the unfortunate client condemned to overcome his natural repugnance inspired by these fearful compounds.

The logical study of the physiological action of drugs has resulted in the elimination of many empirical remedies—often useless, occasionally dangerous—but has also been the means of retaining those among the ancient medicaments whose efficaciousness is unquestioned and arsenic is among them.

The Arabian alchemist Gerber (VIII or IX century) in the *Summa*, describes arsenic as one of the natural principles of the hermetical triad, while other alchemists designate by the name of arsenic the primal matter of the chrysopea; while in the spagyric therapeutics of the physicians of the medieval age arsenic plays an important part, as is proved by the medical theories of Paracelsus, the head of the spagyric school.

It would, perhaps, be absolutely useless to attempt to discover the origin of arsenical medication, and still when the history and genesis of great discoveries are studied, it seems as if science, in its progressive ascent, is nothing else than a perpetual correction of observations and hypotheses willed to us by the generations who have preceded us.

The first indication of arsenical medication is to be found among the most ancient peoples of the Orient. The Hindoo physicians were, perhaps, the first to utilize arsenous anhydrid, and the Chinese, who at the present time employ arsenic for strumous affections and paludism and combine orpiment with mercury in the treatment of syphilis, utilized of old the power possessed by the soluble arsenical compounds of exaggerating intestinal peristalsis and of stimulating the intestinal glands. As an ordinary purge they employ a water charged with vegetable

*Read before the Medical Society of Geneva, February 2, 1921.

acids which has been kept for a time in jars made of arsenical clay.

The arsenical compounds known to the ancients were few, namely, the natural sulphides, sandarac and orpiment or auripigmentum—arsenous sulphide, AS_2S_3 —and arsenous anhydrid or sublimated arsenic whose preparation is given by both Pliny (xxxiv, 18) and Dioscorides. They were used as epilatories and Dioscorides affirms that calcinated sandarac employed by inunction irritates the skin and causes the hair to fall out. Hippocrates used arsenic for its escharotic action, employing the sulphides for this end. Celsus (*lib. V, cap. 7*), Pliny (*loc. cit.*) and Galen (*De fac. simplic. med., lib. ix, 3*), as well as other physicians coming after them, likewise mention the caustic and epilatory action of arsenical preparations.

However, the ancients did not limit themselves to the external use of arsenic and exhibited it internally, especially in diseases of the respiratory tract. Pliny tells us that patients affected with asthma and cough are relieved by inhaling arsenical vapors resulting from the combustion of orpiment and cedar wood, while Desgranges states that Hippocrates used orpiment in purulent expectoration and in hysteria.

This internal arsenical medication was not devoid of danger, and instances of acute intoxication were observed. Dioscorides points out that sandarac and arsenic when taken in a potion produce violent intestinal pain, the intestines being often corroded, and as antidotes he recommends the juice of mallow and decoction of linseed and rice. Therefore it is only natural that orpiment or sandarac and arsenic—arsenous anhydrid—are referred to as poisons by the old writers.

In a Greek MS. at the National Library at Paris, referred to by Delobel, Democritus is made to say to the Prophets of Egypt that the bodies which kill man are the following: Mercury, magnesia, antimony, litharge, copper . . . sulphur, sandarac, arsenic, . . . etc.

During the early centuries of our era the Arabians still employed arsenic as an internal remedy, in the form of fumigations for lesions of the respiratory tract and Avicenna prescribed it in large doses for intestinal parasites (*Tract II, lib. 2, c. 49*).

But arsenic then entered into a period of disfavor, and its therapeutic use seems to have fallen into oblivion; it was regarded as a violent poison. Arnold de Villeneuve states in his *De Venenis* that orpiment causes excoriation of the intestine, while others not only regarded it as a toxic for the human organism but as a mineral poison as well. Arsenic and sulphur are mineral poisons which kill mercury, says Pierre Le Bon of Lombardie in his work entitled *Margarita pretiosa*.

Arsenic proscribed for a time from the uncouth therapeutic arsenal of the epoch, took refuge in the athanor of the alchemists. Albert the Great refers to it as one of the four metallic spirits which can be used for staining metals, in his *Compositum de compositis*, while the majority of alchemists refer to it and describe its properties, but always regarding it as an eminently dangerous substance.

At the commencement of the XV century, Basil Valentin declared that it was ignorance that made the therapeutic use of arsenic dangerous, and in his

Last Testament mentions the danger of poisoning from this metal to which workers in the preparation of arsenous acid are exposed. Then, a little later, Paracelsus declared that arsenic derived all its properties from its poisonous nature, that it was a poison that surpassed all others. And, nevertheless, it was Paracelsus and his followers to whom the honor is due for having brought back arsenical medication into general use, at least for external applications.

Paracelsus attributed a peculiar physiological action to each of the three fundamental elements of Spagyry: Arsenic acts on the blood, mercury on the head and salt on the bones. Each one is eliminated from the body, making its exit by a special route: the pores excrete mercury, the nose sulphur, while arsenic leaves the body through the ears. The followers of the Master advised the use of white arsenic—arsenic anhydride—in the local treatment of cancerous ulcerative processes, a method renewed by Cerny and Trunecek, of Vienna, in the year of our Lord, 1901.

Little by little arsenical medication regained the favor of the medical profession. Jean de Gorris (1503-1577) also used realgar or sandaracha in the treatment of ulcers and prescribed it as a sudorific as well. At the commencement of the XVII century, Angelus Salva proclaimed the arsenical magnet—*magnes arsenicalis, lapis de tribus* (sulphur, antimony, and arsenic)—as a specific against the plague.

Finally, R. Lentilius (1684) and after him, Friceius (1710) in his *Paradoxa de venenis*, advised the use of arsenic in the treatment of malaria. In 1700, a professor at Jena, Adrian Slevogt, and Melchior Frick, a physician of Ulm, praised this metal as a febrifuge, and from this time on the happy days of arsenical medication began.

The drug was prescribed widely in all its multiple forms. Arsenous acid was given internally as well as externally. As an external application it formed the basis of escharotic powders of Father Cosmos, Rousselot, of Justamond and Plukket, Hellmund's ointment and the anticancer remedies of Davidson and Guy, in England, and of Chenet in France. As an internal remedy for cancer, it entered into the composition of the preparation of Lefèvre de Saint-Ildefont (1744-1809), in the Asiatic pills so greatly used at that time for tuberculous leprosy and cutaneous affections and in the powder devised by Plenciz, of Vienna (1783) for malaria. Störk of Vienna (1731-1803) appears to be the only person of authority who opposed the abuse of arsenic in paludism, but the protagonists of arsenical medication were the strongest in the struggle, and in 1786 Fowler, in England, made the use of potassium arsenite popular in the treatment of intermittent fever and overthrew the costly use of cinchona in his book wherein he gives an account of fifty-two cures he had obtained, entitled "Medical Reports on the Effects of Arsenic in the Cure of Agues, Remittent Fevers and Periodic Headaches." London, 1786.

Then came the works of Robert Willan, Girdlestone, and Pearson in England, and those of Valentin, Fodéré, and Desgranges, in France, not omitting the remarkable little book of Harless, of Bavaria, entitled "De arsenici usa in medicina."

Although the great Broussais was hostile to ar-

senic its popularity continued to hold its own in France, England, America, and Germany. Fodéré alone in his "Reserches experimentales," Paris, 1809, gives an idea of the multiplicity of diseases which, at this epoch, were treated by arsenical medication. Among them he mentions hydrophobia, tetanus, angina pectoris, chorea, periodical migraine, rheumatism, chronic bronchitis, and emphysema.

But it was in dermatological affections that arsenic enjoyed the greatest vogue; it was the maid-servant of every skin specialist during the first sixty years of the last century. The English physicians were the first to employ it in dermatology, and as far back as 1806 Girdlestone recommended it in leprosy, prurigo, psoriasis, and tinea tonsurans. Then Rush of Philadelphia, Willan, Bateman, and Fodéré praised it for the cure of leprosy, lichen, eczema, prurigo, and all sorts of cutaneous morbid processes.

3, RUE BELLOT.

The Ideal Feminine Form of the Renaissance.—Richer, the well known art anatomist, has published a book on this subject which is briefly reviewed in *Le Progrès Médical* for December 11, 1920, xlviii 50. As the talented author is a sculptor of no mean ability his writings on these subjects have an unusual interest. As a medical man he was associated many years ago with Charcot in pointing out the relations between pathology and art. We see around us today many girls who have grown too rapidly and have in consequence become weakened. In addition it often appears that they reside in unhygienic surroundings. Conspicuous in their morphology are the rounded back and prominent abdomen. While usually outgrown, this shape may persist in the developed woman. Other features are a poorly developed thorax, sloping shoulders, small breasts of relatively high position, wide hips with pelvis so inclined that the sacrum is almost vertical, and the mons is more prominent than in the normal subject. If now we turn to the sculpture of the Italian renaissance we see in Botticelli's well known model, the beautiful Simonetta who died of phthisis at the age of 22, very similar outlines. There is the double curve of the spine which is responsible for the slightly rounded back, protuberant abdomen, and inclination of the pelvis already described. This form is recognizable throughout the Italian art of this period. In Germany we see it much coarsened in the figures of Albert Dürer, and eventually it degenerated into the impossible. There are other features in these women such as the shape of the hands and feet, the averted modest glance, etc., which have no connection with the skeletal peculiarities mentioned.

Ancient Dietary Rules for Asthma.—The following dietary rules for asthma were printed in the *Magazine of Magazines* for February, 1751.

"If ven'son pastry is set before ye,
Each bit you eat, *Memento mori*.
Your supper, nothing, if you please;
But, above all, no toasted cheese.
The use of vegetables try
And prize Pomona in a pye.
For breakfast, it is my advice,
Eat gruel, sago, barley, rice."

THE GENESIS OF SOME SO-CALLED NEURASTHENIC STATES.*

By TOM A. WILLIAMS, M.D.

WASHINGTON, D. C.

CORRESPONDING MEMBER PARIS NEUROLOGICAL SOCIETY, ETC.

OBSERVATIONS of and reflections upon the neurasthenic patients sent me by other doctors for treatment will show how numerous are the ways in which a person becomes neurasthenic. The principle apparent is the necessity of finding out the process in the patient's body and mind responsible for his symptoms. The restatement of this principle made in 1909 ("Differential Diagnosis of Neurasthenia," *Southern Med. Jour.*) seems still necessary when I read to-day, concerning a much advertised nostrum, the declaration of its proprietor that it is a "tonic in neurasthenic conditions, nervous indigestion, fatigue, loss of energy," etc. An astute business man such as the advertiser does not continue to send such statements to doctors in the expectation that they will not be believed: hence it is evident that enough doctors believe such statements to well compensate this advertiser, who is far from an exception.

We must conclude therefore that there are many doctors who fail to grasp that their crying duty when dealing with a sick human being, and especially a chronically sick person, is more than the immediate relief of the symptoms. It is the dealing with processes bodily or mentally responsible for the patient's suffering or inefficiency. To do this the doctor must understand with what he is dealing. That is the meaning of diagnosis in the real sense. In this sense to label a patient neurasthenic is no diagnosis at all.

CASE I.—Thus a man of 45, too neurasthenic to go to his business (indeed sometimes he could not bring himself to leave the house), after some months of treatment was sent to me by his physician adjudged agoraphobic. In a sense, this is a true designation, but the process by which the agoraphobia has been reached is quite different from the more familiar ones of the type I reported so fully last year, where obsessions were the cause. ("Differential regarding phobias," *Internat. Clinics*, 1919, Vol. IV.) In the case of this man the physical state was really asthenic on account of excessive intellectual and emotional stress for a long period. The over-stimulated endocrines had begun to fail him now and then. His distrust of his power was thus legitimately based upon a physical state, an endocrine asthenia. He was readily dealt with and enabled to resume business while being treated. The chief signs

*The introduction to a symposium "The Neurasthenic Patient" at the first Scientific session in the new Medical Building of the District Society of Washington, D. C., Jan. 12, 1921.

were tachycardia, 100; blood pressure, 140-90; prolongation of time duration of red line; slight, fine tremor; sudoresis; insomnia; feeling of general discomfort and tiredness.

CASE II.—Prolonged stress was responsible for an asthenia of a physicist, which showed itself by inability to concentrate on the abstruse calculations he had to perform. He had been taking so-called nerve tonics for several months without benefit. A study of the case showed a very low adrenal output. Attention to this enabled him to continue his work and in a few weeks to recover his former intellectual resiliency. The blood pressure rose from under 100 to 120 in this time. Subjective discomfort and feeling of unreality ceased and he was no longer anxious about impending failure as he had been.

CASE III.—A woman of 40 was sent to me because of a progressive lassitude interfering with her work, even though requiring little mental effort. She too had been taking tonics because of her inadequacy. The genetic factor, however, had been ignored by her and neglected by her physicians, as it was regarded as almost part of her, so long had it continued. It was a frequently recurring migraine headache. It was the dealing with this which got rid of an asthenia which was only aggravated by the tonics and so-called strengthening nourishment which had been previously prescribed. For methods used see "Treatment of Migraine" in the *Therapeutic Gazette*, 1916.

CASE IV.—A man of 50 lost interest in and power of concentration at his business; he consulted a doctor who prescribed a tonic and advised rest. This only made him irritable, as insomnia is troublesome. Examination showed hyperproteinosis with a raised blood pressure. Dietetic and other measures rectified this and his asthenia rapidly ceased. (See "Nervousness and Presclerotic States and Their Management," in *Lancet Clinic*, 1914.)

CASE V.—A young woman became unable to concentrate at work, which furthermore did not satisfy her aspirations. The long continued intellectual asthenia was found to be based upon a lack of social and emotional outlet, with an accompanying endocrine inadequacy due perhaps to the long stress under which she had labored. Dealing with her adjustments to life transformed her personality, while asthenia no longer played a large rôle.

CASE VI.—A woman of 40 was sent by Dr. Lewellys Barker with a comprehensive diagnosis in which the word psychoneurosis plays a part. The domestic work which falls upon the wife of a doctor in a remote region cannot be done without a pain in the back and the right lower limb. Medical advice, regarding her as a neurasthenic, had caused her to persevere in spite of this. Careful study, however, showed the sequelæ of a definite radiculitis of the 5th lumbar root caused by a former arthritis of the lower spine, the traces of which are no longer revealed by an x-ray picture. The signs permitting the affirmation are the location of the painful sensation, the curtailment of the period during which the vibrations of a tuning fork played on the bones are felt and the inability to distinguish two points simultaneously touching the skin over the distribution of the right fifth lumbar root as compared with the left. To deal with the radicular condition is to improve the asthenia, which is not an excuse to evade unpleasant work or a sham defense against it, as a one-sided physician might persuade himself, if an uncritical reader of psychopathological literature and ill grounded in organic neurology.

CASE VII.—A stenographer became progressively weaker and less able to perform her work, which rendered her more and more irritable, and she began to sleep badly mainly because of a gnawing pain in the shoulders and lower neck. Her physician detected no physical signs and treated her by the tonics unfortunately too usual. Examination discovered that the whole syndrome was really secondary to the pain in the neck and that this was due to a faulty stooping posture at the keyboard. A few exercises with attention to posture at work removed the pain, and the asthenia ceased for a period of eight years.

CASE VIII.—A former aviator who had a severe crash, although declared to be well on discharge, found himself unable to concentrate at mental work, which made him more and more irritable and induced again convulsive attacks which had ceased in hospital. The tonics and diet given in consequence of the theory that the symptoms proceeded from a nerve weakness which would be compensated by a highly nutritious diet only made him worse. A deobstruent diet and active work in the open air enabled him to continue at work fairly satisfactorily. He is now in business in town and manages without further breakdown.

CASE IX.—A young woman in a pitiable state of emaciation and asthenia who had manifested convulsive attacks on account of which she was submitted without benefit to an abdominal operation along with a fantastical diet which had contributed largely to her extreme asthenia, was seen in a state almost of collapse, in spite of which she was being urged to exertion, in the belief that *neurasthenia played a large part in her state*. Examination revealed definite signs of a neoplasm apparently beginning in the cortex of the right insula.

CASE X.—Almost complete inability to concentrate and remember his lines was the chief complaint of an actor, leading man to a famous woman star. His behavior was that of the so-called typical neurasthenic. Examination, however, showed that the real condition was a phobia which had been induced by an unfavorable criticism followed by a rebuke from the star. After I saw him through a special rehearsal, the power to concentrate and recollect his lines returned and the rest of his engagement was successful.

CASE XI.—Another leading man found himself in the same predicament; but the cause in his case was intense anxiety due to an ill-founded jealousy of his wife. The situation was highly complex and had to be gone into in detail with both parties, after which the man was able to undertake successfully an important engagement without further trouble.

CASE XII.—A young woman was reduced to a pitiable state of exhaustion on account of long continued fear lest she find herself alone in a room. She had spent four months with a psychoanalyst without benefit. Two interviews at her home sufficed to trace the fear to its inception in childhood and to enable her to take a much needed holiday at the seashore, which greatly improved her asthenia, although she has been unable to visit Washington in order to complete the psychological reorientation.

CASE XIII.—What is considered as a neurasthenic vice, viz., a detailed writing of one's symptoms in order to retail them to the doctor is one of the attributes of a young man sent by Dr. Brill of New York because of an asthenia along with nocturnal incontinence, for which psychotherapy availed nothing, as a wetting occurred nearly every night. Examination revealed numerous signs of vagotonia. The treatment has enormously improved the asthenia, so that for two months he has continued at work and has only wet himself once.

The garrulousness of the neurasthenic has become a by-word. It is now being dubbed an "infantile reaction," a short sighted designation, for children do not expatiate upon bodily distress. They prefer, like the animals, to retire from disturbance, and groan and weep if they make any complaint at all.

The plaints of the neurasthenic are not from self love; it is not that which animates his conversation, but the desire to understand, with the very practi-

cal object of getting rid of discomforts. They are only searchings for interpretation of his discomfort. A wise doctor has little difficulty in curtailing them, but this he does by a leech-craft which guides him quickly to the essentials. After these are interpreted, the patient complains no further, being satisfied.

I need only mention such frequent and well-known causes as focal infection and latent tuberculosis or syphilis. Less realized are the metabolic disturbances, in which perhaps we shall have to include hypovitaminosis. (See Diet in Psychiatry in Fitch's "System of Dietetics"; also see Trans-Am. Medico-Psychol. Assoc., 1917.) There must also be mentioned the mild cardiopathies, and of course the endocrinopathies (see MEDICAL RECORD, April 14, 1917, p. 623) upon which I have scarcely touched, as well as mild psychoses.

For instance the milder cases of cyclothymia especially in the depressive phase are nearly always treated by injudicious medication and strychnine and other tonics, while in the exalted phase of the condition they are given bromides and other depressants. To say manic depressive, however, is no therapeutic help, but some neurologists are now experimenting clinically in these cases which wear many aspects of endocrinopathy of cyclical course.

CASE XIV.—Thus a lawyer of forty-four, sent by Dr. Payne of Virginia has been under observation for over four years and has been kept at work by opotherapy, chiefly adrenal, all that time in spite of several severe attacks of depression of a kind which had previously necessitated staying in sanatoria for months at a time. In one clinic much work was done by a skillful man in a vain effort to elicit a buried complex (non-existent) to account for his state.

Dyspituitarism too is often responsible for a diagnosis of neurasthenia.

In some so-called neurasthenics, the chief complaint is of uneasy sensations, usually in the chest, abdomen, or pelvis. Those physicians who, without adequate neurological training, are greatly enamoured of psychic mechanisms, are fond of attributing these sensations to the imagination by a process they call conversion by which they mean the referring of a mental distress or uneasiness to some region of the body, to which the patient then attributes the discomfort. Now this mechanism may occur whenever the bodily accompaniment of an emotion draws the patient's attention to the part, especially when it is fixed there by the suggestion of friend or doctor. But these conditions are not hard to unravel, and can be dealt with psychotherapeutically.

The inexperienced man fails to distinguish them from the cenesthesiopathies, that is where morbid sensations really originate in the viscera to which the patient attributes them. The difficulty is created by the vagueness and indefinite localization of these sensations, so they are often erroneously attributed to imagination and labelled hysteria. They are vague because it is the protopathic sensibility which is concerned, subserved by the autonomic nervous system, which has not a localizing function and the afferent impulses from which are rarely attended to. Their disturbance, however, creates an uneasiness which is sometimes intolerable. Unfortunately we have no definite therapeutics in these cases.

Between the emotional consequences of this un-

easiness and the physical consequences of emotion the greatest expertness is required to differentiate. Differentiation cannot be expected of a physician whose outlook is purely psychological nor of one devoted to a physiological theory of the neuroses, not even if he has much experience as an internist. Even some psychopathologists are placing too much emphasis upon the emotion itself, rather than going behind it to its origin, as I pointed out at last year's meeting of the American Medical Association ("The Causes of Emotivity and Their Management," *Jour. Amer. Med. Assn.*, Aug., 1920; see also *MEDICAL RECORD*, March 5, 1921.)

The emotional drama itself is unimportant to the physician; but the actor who performs it, whether the heart, the thyroid gland, a microorganism or a wrong way of thinking must be his paramount aim.

It must not be forgotten that the neurasthenic syndrome is not an inevitable upshot of any of these conditions. "For that which is but a fleabiting to one causeth insufferable torment to another; and that which one by his singular moderation, and well composed carriage can happily overcome, a second is no whit able to sustain, but upon every small occasion of misconceived abuse, injury, grief, disgrace, loss, cross, humor, etc. (if solitary or idle), yields so far to passion that his complexion is altered, his digestion hindered, his sleep gone, his spirits obscured, and his heart heavy, his hypochondries misaffected; wind, crudity on a sudden overtake him, and he himself is overcome with melancholy." This qualification is far from new, as it was said as long ago as 1621, by no less a person than Robert Burton in the famous *Anatomy of Melancholy*.

In the cases cited I have not laid emphasis upon the false neurasthenics of the type so abundantly described by Déjérine. I refer to those in which affectation or direct imagination is the causative agent. The psychogenetic cases I spoke of are of the kind where mental prepossession, anxiety, fears, anger, grief, suspicion, uncharitableness, envy, or hate produce disadaptations. These may weary the organism through effects upon digestion and other secretions, as well as upon respiration and circulatory functions. It has been well said, "Better a crust where contentment dwells than to feast in the seats of the mighty."

It is lamentable, in view of the facts just set forth, which have been repeatedly reiterated and ought to be completely known, that there are still medical men whose conceptions of neurasthenic states are so defective as to permit them to believe in the obsolete shibboleth of nerve exhaustion and who prescribe so-called fortifiants or tonics without troubling to ascertain the processes occurring in the patient's body or mind. For that is no better than the untrained amateur or the charlatan.

Let me conclude by making the appeal that when speaking to the laity at least we delete from our vocabulary the reprehensible word neurasthenia.

1746 K STREET.

Organotherapy in Cerebrospinal Meningitis.—Mery and two others report a case of cerebrospinal meningitis due to the meningococcus, which had culminated in a severe cachectic state. There was no response to serum, autovaccination, or fixation abscess, but a prompt recovery under extracts of hypophysis and suprarenal gland.—*Le Bulletin Médical*.

FADS AND FASHIONS IN MEDICAL PRACTICE.

BY FRANK E. WYNN, M.D.,
INDIANAPOLIS, INDIANA.

THE terms fad and fashion are related in meaning but vary widely in application. The former has rather a restricted significance. A fad is an individual thing largely; fashion has for its votaries a large number—sometimes the multitude. Fads are transient in duration; fashions extend over a longer period of time and exercise a widespread influence. Fads initiate new things which may in time gain the momentum of popular approval, entitling them to be called fashions; and succeeding fashion the long continued use of a thing, a method, a habit, an idea, establishes it as a custom of the people.

The faddist is enamored of new things, but his affection for them soon wanes and his fancy goes chasing after some other flame which illumines his vivid imagination. In childhood this characteristic is dominant. It prevails in all of us to a greater or less extent. In some intensity of the trait persists throughout life.

The faddist is generally of the alert type, often artistic or strikingly intellectual. He has inordinate craving for mental stimulation. He is to be found in every avenue of human activity of the higher type. In the realm of literature he at one time develops unbounded enthusiasm for Kipling; presently it is the star of Tolstoy which is in the ascendant; for a time he pays extravagant devotion to Bernard Shaw; next bows before the shrine of Blasco Ibanez; and now makes deep obeisance to the poetry of Edgar Lee Masters. In the field of art his imagination finds greatest delight at one time in the works of the impressionist school; at another he is carried away with the grotesque productions of the cubists. The faddist prevails in politics, quick to condemn and abandon existing methods and just as quick to be caught up by some new and untried remedy for political ills. In the field of religion and education he welcomes with delight striking innovations, and views with ill-concealed disgust the conservatism of old methods. The slow-going world is the better for these aggressive individuals who call attention to new and suggestive things, even if in the long run many of them are found useless or harmful. Faddists sow the new seed, but it remains for the conservative and more critical judgment of the average mass of mankind to harvest the good grain and cast out the chaff.

What, then, of medical fads? Being human, is it to be presumed that we are exempt from our full quota of faddists? Literature, art and music, being temperamental accomplishments, naturally have a large proportion of faddists. Medicine, on the other hand, with its matter-of-fact ways of critical observation and analysis, has less dreaming, and perhaps less faddists, and yet a surprisingly large number.

In not a few medical men faddism takes the form of raiment. What a delight they find in the newest cut of coat, or a stylish hat; or again the same impulse finds outlet in an impressionist style of new automobile. Let us admit this is simply personal vanity, not without virtue, how-

ever. Certainly it is less to be condemned than slatternly dress, or uncouth acts—ill-mannered affectation sometimes assumed by physicians, which is as much a fad as the stylish clothes of the dandy.

In others this same spirit of craving for novelty and distinctiveness takes the form of speech. Such a person discovers a new word in medical literature, which he parades as another would his stylish clothes. In pronunciation, too, he finds a favorite avenue of expression. Scarcely had we come to pronounce with ease the word *bacillus* when he proceeds with great emphasis to jar our ears with "backeillus." From a sojourn in the East he brings home the broad sound of "a" to clash with the short, flat "a" of our Middle West, so that when he says *class* we scarcely recognize the word. He chants it with the same dignity that a choir would sing an anthem. These sallies of incidental instruction always rivet one's attention. But the medical man who is a votary of faddism in pronunciation of course runs great risk of diverting attention from the main theme of discussion. However, since it affords him such manifest pleasure and instructs his auditors, why should complaint be offered?

Akin to the pronunciation fad is the apparent delight an occasional physician takes in giving to a new sign or symptom the name of the author who has described it. How mystifying the name! Why rob the newly discovered sign of its charm by a commonplace designation which would give inkling of its nature and recognition? He always refers to Grocco's sign; never to the paravertebral triangle.

Faddism is inherent in most of us. It is chiefly a question of degree. Who, for example, has been able to resist the impulse to fly off at a tangent now and then in therapeutic procedure? A new remedy is promulgated from a great pharmaceutical establishment—heralded in suggestive phrases. The flare of promise illuminates our imagination. It is the temptation to gamble. We stake our hope on it. We prescribe it, talk about it, and coddle ourselves into believing it is of value. Presently we see things more clearly, enthusiasm wanes, and by and by our pet goes into the discard. Then our attention is attracted to another therapeutic rocket fired into the professional sky. So one after another of these therapeutic will-o'-the-wisps is chased—phantoms which seldom bring substantial realization. The keen business acumen of the manufacturing pharmaceutical houses is constantly tempting us with these things. What infinite variety they place before us! Infinitude alone indicates the limit of new things they will continue to present to lure the unwary. Here is where most of us have been faddists—often to our later shame and the discredit of the profession. Who of wide experience can escape the charge of guilt in this respect? Should we not more generally resist the faddish impulse to therapeutic experimentation at the bedside? Here of all places we should be governed by the work of painstaking investigators of pharmacologic products—able clinicians with ample facilities and laboratory men of sufficient ability to justify our faith in their conclusions.

Since the advent and multiplication of laboratory methods of diagnosis not a few physicians have become faddists in their use. I would not have the reader misjudge my estimate of the extreme value of these methods as aids, sometimes indispensable, to diagnosis. The point contended for is that we have too often been prone to magnify their importance; not infrequently allowing them to push into the background other procedures of even greater value. The physician gets into the habit for a time of pursuing a one-track route to diagnosis, when he might arrive at the diagnostic haven by other roads, more certain if not so spectacular or short-cut. The aeroplane is the quickest route across the Atlantic, but steamship offers a safer passage. Too often we have faddishly emphasized the microscopic diagnosis of new growths, cultures for the recognition of diphtheria, gonococci for the proof of specific urethritis, tubercle bacilli for pulmonary tuberculosis, Widal for typhoid, Wassermann for syphilis, x-ray for gallstones, and many other special, technical methods, when our business as physicians taking a broad view of medicine should be, not to overload these special things with responsibility, but to assemble with care clinical data for the foundation and superstructure of diagnostic truth. Then let this be illuminated by every possible light of special medicine.

The study of fashions shows that they are uniformly wavelike, beginning in a small way, rising gradually to a crest of popularity, and then receding into disfavor, or abandonment. The chief psychologic forces making for their growth are: first, the universal craving of the human mind for novel excitement and entertainment. Secondly, through the massed suggestion of numbers, reacting upon each other, the wave of popularity is given tremendous momentum. The life cycle of fashions is variable. Style of dress in the feminine world is rapidly changeable—less so among men, as note the century-long popularity of the dress suit. Less frequent but just as characteristic are the wave-like movements in the manners of social life—the forms of salutation, speech and written address; the changes in dancing and other recreational amusements. Needless is it to multiply illustrations. It matters not what particular field of human activity is considered, the same psychologic elements of fashion will be found present directing and controlling to a large extent those who make up that following. The medical profession, therefore, is governed by the same laws of fashion as other classes of society. True our scientific training should make us less susceptible to fashion waves, yet close analysis of the facts shows that we are much like other folks.

The influence of fashion in medical practice is well-nigh irresistible. The mass suggestion, the fact that professional opinion is running one way, leads most of us to drift with the current. It is not merely that other physicians are doing thus and so that we fall in with the majority; the laity push us into the current with the humiliating taunt that we are laggards or slackers if we do not get into the swim. The principle is the same as that which compels us to change the style of

our clothes or be considered queer and a back number.

Almost every new style in medicine has had some practical or scientific basis for its inauguration. Beginning in a small way, its volume increases to a flood, carrying the rubbish of misuse or abuse, followed by subsidence of the wave of professional approval, or perhaps the drought of abandonment. Only a few of these are offered in illustration. Nearly all of them relate to therapeutic procedure. They carry some good just as they are impregnated with some bad—representing the wobbling, struggling effort of fallible human beings toward better things. The problem of prime importance in regard to any fashionable movement in medicine is to conserve in the end the elements of good—and guard against the natural reaction of condemnation and abandonment. Some of these movements are limited in extent and transient in duration; others take deep hold upon the profession, become the universal practice, and so established in respectability, that not to follow them is to be a medical heretic.

A very dominant medical fashion during the early part of the past century was phlebotomy. Any practitioner who ventured to question its value was professionally ostracized or condemned as derelict in duty. For many years it held sway as the most useful therapeutic procedure. Such was the verdict of careful students and practitioners of the time. Yet note the gradual decline of its popularity and final abandonment. Are we to conclude that they were entirely mistaken in their judgments? On the other hand, are there not very good anatomic, physiologic, and pathologic grounds for performing phlebotomy in certain cases—as for example uremic coma, cerebral hemorrhage associated with high blood pressure? Yet who has the courage in these days to advise phlebotomy? Strange, is it not, that so intelligent a profession should be so dominated by reactionary prejudice.

The overweening pursuit of drug therapy has constituted more than a fashion. It has become a professional custom, bolstered up by prejudice which it is difficult to shake off. Born centuries ago in an age of mysticism, even time and unemotional science have made slow progress in getting the light of progress through the thick skin of our superstitions. The lay-world bows before the shrine of drug therapy—looking longingly for the Fountain of Perpetual Youth or a mysterious potion which will work a miracle within the body. These words are not to be construed as a condemnation of drug therapy *in toto*; but a plea for the use of drugs upon proved, rational grounds. The driving impulse to search after the mysterious potion, which will restore health, is not unlike the human longing for life hereafter. The *urge* points toward truths which may some time be revealed. In drug therapy a few precious revelations have been made. Experimental pharmacology in our own day has brought to light many therapeutic facts of extreme value. Let the search go on, to bless coming centuries with other discoveries, wrought out of patient experimental toil. But this does not justify the profession in making a fetic of drug therapy, as

do laymen who are biased through the inherited mysticism of past centuries. The quack recognizes this tendency of the race, and accordingly makes appeal to credulity through the mysteriousness of his nostrums. Pharmaceutical manufacturers cater to this same racial tendency in the medical profession, inundating us with proprietaries and new products bearing alluring titles and suggestive promises.

Polypharmacy has constituted the most conspicuous aspect of drug therapy and its worst sin. Even to the present day its influence is felt in the complex formulæ of proprietaries and official compounds, although a strong and wholesome tendency exists toward simplicity in drug administration, not characterized by the enthusiasm, however, which entitles it to be called a fashion.

A fashion of the last century growing out of and in a measure succeeding to, multiplicity of compounds, was magnitude of dosage. "Doctors of the Old School" still amongst us, tell interesting narratives of the large doses formerly employed, notably in the administration of mercury. In protest arose the sect of Hahnemann advocating minimal dosage and specific medication—erratic extremes in opposition to prevailing practice. This served a useful purpose in breaking the high wave of excessive dosage and nauseous mixtures. So has come to decline this therapeutic fashion.

As the wave of fashion for large dosage and bulky, nauseous mixtures subsided, another arose, supposed to correct the old abuse—namely, coated pills and tablets. Three important agencies have combined to promote the popularity of this type of medication. First, patients preferred tablets to the nauseating compounds; secondly, they proved a convenience to physicians, especially those who were compelled to do personal dispensing; and thirdly, the pharmaceutical manufacturers seized upon pill and tablet production as a lucrative avenue to business success. That this plan of drug administration has distinct advantages entitling it to a place of permanency cannot be doubted. Admitting its virtues it is just as important to give serious heed to dangers lurking in the method. Who can deny, for example, that the manufacture of innumerable formulæ in pill form has tended to destroy initiative and skill in the art of prescribing? In the next place the multiplication of manufacturers has put upon the market many pills and tablets which are inert; or even granting virtue in their composition, they may be so combined, desiccated, or compressed as to render them insoluble. Very recently a most intelligent patient made special request that I should not prescribe tablets made by a very well-known pharmaceutical establishment because on two different occasions he had found the tablets passing by the bowel almost unchanged.

A very real danger is that the physician will acquire the pill-vending habit. He becomes more a tradesman than a physician. It encourages office dispensing, which at first thought looks attractive, but in the end leads laymen to think of the doctor as a man peddling wares. They naturally reach the conclusion that they pay for medicine rather than advice. The ultimate effect

is a lowering of professional prestige. Pill and tablet prescribing is a prevalent fashion which calls loudly for reform. It is producing in the ranks of the profession a host of therapeutic nihilists. Out of the infinite variety of tablet formulae which clutter his office the physician comes finally to lose respect and confidence in drugs. He drifts into the attitude of saying to himself, "O well, one thing will do as well as another." The urgent call of the hour in regard to this fashion of our time is not for abandonment of tablet therapy, but for the production of trustworthy products and simplified composition. And, above all else, the pill and tablet craze should not be permitted to usurp the place of art in prescribing other things and methods which will better achieve the relief of the patient.

In Jenner's great discovery, with its scientific suggestiveness and vast practical benefits, the soil was fertilized for the growth of even greater rewards in the prevention of disease and the advancement of therapy, through the revelations of pathology inaugurated by Pasteur and his followers. The outcome has been the rapid development of the system of biochemical therapeutics. Antitoxin led the way. Its great practical value in the cure of diphtheria proved, hope was aroused for similar benefits in other infectious diseases. It attracted at once the most noted pathologists, pharmacologists, and clinicians, who have been endeavoring to work out scientifically the control and cure of different infections along similar lines. Great pharmaceutical houses have expended enormous sums in the erection, equipment and manning of laboratories for the purpose of manufacturing biologic products for the treatment of disease. Antitoxins, serums and vaccines of infinite variety have been produced. An expectant profession has been taught to have faith in these things notably by their experience with diphtheria and tetanus antitoxin; also from the occasional aid by the judicious administration of tuberculin in incipient pulmonary tuberculosis, as well as some other forms of Koch infection; again by the obvious benefit noted in some types of gonococcus infection; and quite markedly in certain kinds of local infection by autogenous or even stock-vaccines, when the general body resistance is good. These conspicuous achievements have caused the wave of biochemical therapy to rise very high in professional esteem. Encouraged by experience to have faith in the movement it is not strange, therefore, if the profession should be dazzled by the brilliancy of accomplished things, and go blindly about the further application of the plan in therapy. This form of treatment has become a predominant medical fashion of our day and generation. As in other fashions, may it not be true that we are now being borne upon a wave of enthusiasm in which unwarranted excesses are being committed? The injection of a foreign protein into the body is never to be taken lightly. The indiscriminate use of vaccines especially is not only unscientific, it is senseless and fraught with grave danger. Of course no account is here taken of those who use vaccines with venal intent—merely because popular, spectacular, and

a form of therapy in which considerable fees are possible. Such a person is no better than the most arrant quack. This appeal is made to the man who is carried away by the wave of popular approval of this form of therapeutic procedure. The injudicious and unscientific application of the treatment can only bring harm to many patients and embarrassing discredit upon the profession. The tocsin here sounded, then, is greater caution in the use of these measures. Make sure that all the indications are present calling for their application—then use them but with the care which will avoid harm and insure benefit to the patient.

The Council on Pharmacy and Chemistry of the American Medical Association has done a conspicuous service in trying to correct the harmful trends in vaccine therapy. The volume soon to be issued by the Association will prove a most valuable and reliable guide to the profession in this popular and useful phase of treatment.

For consideration last has been reserved a medical fashion destined to wield a greater influence than any which has preceded—operative surgery. From century-old practices of the art it has arisen triumphantly in spite of deepseated lay-prejudice. Bacteriology first laid the foundation for aseptic surgery, and experience soon emboldened the operator in surgical attack. So dashing have been the battles won that not the profession alone, but the world as well, stands in awe and admiration of the achievements. So won over to operative procedure is the public that now the layman's query in perplexing cases is apt to be: "Would an operation offer relief in such a case?" Thus has grown faith, based upon works. Among general practitioners the ultra-conservative have been driven by popular opinion to espouse more aggressive, life-saving tactics; and some practitioners have been charged by a critical public as slackers and laggards in the professional procession, because slow to accept the surgical route to relief.

The final yielding of the reactionary elements in medical practice to aggressive surgery has come about chiefly through the slogan of focal infection. With the rising wave of surgical fashion, one after another anatomic region has been invaded by the knife, with sanguine hope of relieving both the local and general symptoms. Amongst these may be mentioned in sequence the ovaries, tubes, appendix, gall-bladder, tonsils, mastoids, and teeth, each of which has been charged with blame for the systemic manifestations. Often the accusation proved true, for relief followed surgical attack upon the suspected focus. In such cases we justly congratulated ourselves upon the wisdom of the course pursued. But we must be just as honest in acknowledging failure in not a few cases—in truth some show an aggravation of general symptoms (in the heart, joints, kidneys, etc.), and in a few, grave conditions are provoked. Let us not, then, with thoughtless minds or unfeeling hearts make unseemly haste to advise surgery. One needs not to search far to discover in the evolution of this fashion excesses which shame us as we look back at them. Who will ever be able to compute the

ovaries which were uselessly sacrificed two or three decades ago? In the light of this experience does it not behoove us at this time to enquire, if perhaps in the matter of the tonsils and teeth we are not repeating the same unwarranted slaughter of parts which should be more frequently conserved? Let not these words be construed as a protest against justifiable surgery; rather let it be considered an earnest appeal for that thorough study of cases which warrants surgical procedure. In proof of the contention here made three examples may be cited from the records of patients admitted to the Robert W. Long Hospital, during the month of February, 1921. The histories of these cases show a long list of operations all performed in other institutions with one exception—tonsillectomy.

CASE I—S. M. Single woman.

At age 23, cystic ovary removed on the left side.

At age 24, left ovary, tube, and appendix removed because of pain in the side. A sinus resulted which required several operations to secure healing, extending over two or more years.

At age 25, one breast was amputated, because of tender and infected lumps.

At 27 the other breast was removed for similar conditions.

At age 30, admitted to the Robert W. Long Hospital. Complaint: pain low down upon either side; nervous and hypochondriacal.

Chronic amygdalitis diagnosed—tonsils removed.

Discharged unimproved.

At age 31, readmitted to hospital, pains of indefinite nature through bowels; occipital headache. Discharged unimproved.

At age 32, readmitted to hospital, complaining of pain in the stomach and bowels. Final diagnosis: psychasthenia with mental inferiority.

CASE II—J. S. Male.

June, 1919, operated for suspected gall-bladder trouble. Again operated in December, 1919, for adhesions, supposedly following the previous operation. June, 1920, another exploratory operation was done in an eastern hospital without finding anything definite.

February, 1921, patient was admitted to the Robert W. Long Hospital showing all the typical subjective and physical symptoms of a tabes dorsalis, with serological findings positive.

CASE III—E. G. Male. Appendectomy done in 1916.

Operated upon in July, 1917, for duodenal ulcer; gastroenterostomy done.

November, 1917, plastic operation done to relieve contracture.

June, 1918, duodenal ulcer excised.

May, 1920, old gastroenterostomy cut off, and gastrojejunum ulcer excised.

January, 1921, admitted to Long Hospital with severe epigastric crises. Laboratory and clinical findings were conclusive for tabes dorsalis. Query: May not all of the conditions for which operations were performed in this case have been luetic?

These errors, superficial study of cases and precipitate appeal to surgery, constitute the gravest danger growing out of the dominant fashion for operative relief. In the long run it can but react harmfully upon legitimate surgery.

Besides these sins of omission and commission, are there not perhaps other dangerous channels into which the prevailing fashion may be leading? For example, while the strict application of asepsis makes the able operator bold, it is apt to lead the incompetent to reckless extremes, resulting in human sacrifice. The simplicity of aseptic and surgical technique in the main has tended to produce an army of technicians, with-

out breadth of surgical grasp or the wisdom of surgical judgment. False standards are set up, cheapening both the art and science of the profession. The call of the hour is not for less technicians but for more real surgeons, who pin their faith to a working knowledge of anatomy, physiology, surgical pathology and the ability to deal with problems and emergencies in the light of this knowledge. Subsidiary to these, but very important of course, is thorough training in the mechanical phases of the art.

Begotten of surgical fashion, is observed not rarely, the sin of arrogance. Surgery has dramatic appeal to the lay-mind. The egotism of the operator is fed by popular acclaim. The less spectacular general practitioner sometimes becomes moody and envious, charging the public with ungratefulness. The surgeon is prone to conceit and self-sufficiency. Who would have the temerity to question his wide experience? He has seen hundreds of cases of appendicitis; why then should the general practitioner suggest the possibility of beginning pneumonia with pain referred to the abdomen? Would it not be interesting to know how many gall-bladders have been drained in tabetic cases with abdominal crises? The writer can enumerate a considerable list. Sometimes the general practitioner is justly blamed for dallying when aggressive surgery would save life; and I can say with equal truthfulness that I have seen perfectly healthy ovaries, appendices, tonsils and teeth removed. That these things happen is to the credit neither of the one nor of the other. The exhortation is for greater diagnostic care and closer co-operation.

An outgrowth of the prevailing surgical fashion in quite a few men has been the development of the vice of avarice. The trend toward big business the world over has too often taken hold upon the surgeon. The modern hospital with its equipment and system has enabled him to concentrate and facilitate his work. It offers likewise better opportunities for scientific endeavor as well as surgical relief. It is an evil day for him if once he becomes infected with the germ of avarice, for the malady is difficult to cure. His consuming thought then becomes "big business"—many cases and large income! Assistants make preparatory study of his cases and take entire charge of the post-operative management. He is prone to lose personal touch with patients and develops into a cold-blooded materialist. He becomes a brilliant technician and operator, known to the lay-world chiefly by his fabulous income. His career takes on a mercenary aspect. He loses in skill of scientific approach to the operative attack and fails to cover disease retreat against the dangers arising in convalescence—thus neglecting one of the main principles in first class generalship. Fine assistants he may have (perhaps better than the chief himself) but the point is that he is passing for something which he is not. The three indispensable links of operative surgery are, thorough diagnostic study, the mechanical phase or operation, and the post-operative management. "Big business" prompted by avarice will seek to get by with the operative link only. This is not fair to the patient; it is

worse for the surgeon, who is neglecting the intellectual, judicial, and human side of surgery for its mechanics, its narrow materialism, and "big business."

It will be quite generally admitted I think that the outstanding fashion of medicine for our own day and generation is operative surgery. That it has shed imperishable luster upon the profession, who can deny? But like any rising wave of fashion, some drift is carried along with the fine ships of achievement born upon its crest. This is to be expected in any case remembering the fallibility of human wisdom and human judgment. Is it not meet therefore that we should take counsel one with another about the dangers? Most of all, is it not incumbent upon those prominent in the surgical field to sound the note of warning? Is not the human body a sacred temple of which we are the earthly custodians? Shall we permit defilement of this sanctuary without due preparation and reverence for its wonderful mechanism? Does every new focal symptom constitute sufficient warrant for rushing to vaccines or surgery without adequate study of the case from every angle, with a summary of conclusions, justifying the one or the other procedure? In other words, the route which every conscientious practitioner should follow is that of painstaking, scientific inquiry and not always the highway of fashion. There may be other roads safer, better, and more direct to the haven of health for the sufferer. Our highest duty is to ascertain the best route and pursue this steadfastly.

421 HOME MANSUR BUILDING.

THE NATURE OF EDUCATIONAL HYGIENE.

BY IRA S. WILE, M.D.,
NEW YORK.

EDUCATION connotes the systematic development of latent powers so as to create a maximum of special or general living efficiency. As a process, it aims to cultivate the relations of the individual to the ideals of the community. In its methods it seeks to foster the intellect, the emotions, and the will so that they may harmonize in right living. Through exercising, creating, and stimulating activities, by stabilizing beneficent habits, and through motivation from interest and enthusiasm it seeks to extend all forms of human experience so as to establish a character by reason of which egocentric and altrocetric desires may function without friction. Thus education tends to draw out and build up latent human capacities—physical, mental, moral, esthetic, vocational, and racial.

Hygiene is a branch of medical science that is concerned with the preservation and improvement of health for individuals and for communities.

It is undeniable that education deals with the mass as well as with the individuals. The teacher, the physician, the nurse, and the school visitor, with varying degrees of prominence, function in the educational process. In its hygienic aspects education takes cognizance of the general supervision of the community, and is equally interested in the examination and conditioning of individual children. There are, naturally, variants in all communities due to the presence of abnormally, or

preferably, atypical children, who themselves create educational and hygienic problems involving the progress of normal children.

There is a common ground, then, of education and hygiene which may properly be termed Educational Hygiene. It does not represent a dilution of medicine applied to an educational system, but rather the cooperation of medicine with educational systems. Both are concerned with methods of prevention and remedial agencies for the promotion of the welfare of the child at school. Both are concerned with problems of brain power, fatigue, latent ability, and inherent vitality. Both serve childhood and recognize the interrelation of work, play, and rest with physical limitations, mental impairments, and moral tendencies. Education assumes the expansion of a certain average of physical wellbeing, and is now concerned with the methods of raising that average. Its relations to hygiene are no longer narrowed to the acquisitive function of the brain, but involve an understanding of all the physical factors that underlie educational processes.

O'Shea for many years has urged the necessity for the development of the "scientific temper among teachers, and the adoption of scientific methods by all who treat of educational questions." This position is further urged by Horne, who tritely expressed what is now a common view: "Every indispensable qualification of the teacher, viz: a knowledge of the subject taught, the ability to teach, and a worthy character." It is patent, that a knowledge of the pupils taught, and the ability to teach are, in a large degree, dependent upon an appreciation of the growth and development of childhood. Rapeer in his "School Health Administration" enumerates under the head of medical supervision, School Sanitation, Physical Education, Teaching Hygiene, and Hygienic Teaching, and a vast array of subjects in which education is shot through with hygiene. There is no hiatus or dissociation of the two general subjects, but they are more or less unified by a point of view which enables each to take advantage of the other, so that a harmony is secured that reacts beneficially upon the pupils, the teachers, and the community interested in the successful organization of child welfare.

It may be said, that the professional pedagogue should be the responsible judge of the weaknesses in our educational systems. This is a phase of professional spirit narrow in its conception, and unworthy a professional mind seeking light upon all its problems. As an illustration of the folly of this point of view, one may point out the disadvantage of having medical observation only remotely connected with the work of the teacher. Medical observation cast into the school as an extraneous function achieves inadequate results. Greater gains result when teachers are not merely capable of discerning variations in educability, but are interested in understanding their causes, and become active in aiding the discovery of the basic variation responsible for educational failure. This does not mean that a teacher must assume the functions of either a doctor or a nurse. Hygiene is not devoted merely to the recognition of disease or defect, but concerns itself with the remedying of handicaps, and what is more important, the prevention of their development.

If one considers educational morbidity and mortality as evidenced in truancy, retardation, and elimination, one faces the paucity of our present day application of the scientific temper. What is the efficiency of an educational system that holds only 60 per cent of entering children until the eighth grade is reached? Or the sixth? What is wrong if only about one-third of our school children graduate from an elementary school of seven grades or more, and less than one in ten graduates from a high school? Where is the difficulty? Does it suffice to say that the present courses fail to hold interest? Or that children appear to be incapable of accepting the intellectual provender now provided? How much information and explanation is derived from the report of an attendance officer who accounts for absence under these heads: Illness, illness in family; kept at home to work; out of district; unclassified; found on street? Is there sufficient information here for a consistent plan to lessen absenteeism, or to formulate a scheme for the reduction of truancy? Is there any advantage derived from these general expressions concerning delinquency, unless there be more specific information here concerning the underlying causes? What part is played by the homes of poverty, not merely financial, but poor in happiness, poor in culture, poor in peace? How much is due to lack of parental care, parental interest, parental understanding, indifference, neglect? What is the influence of contact with pleasure, candy, cards, smoking, indecent literature, and gang life? Wherein does the physical condition or personal temperament function? What are the particularized results of adolescent instability, school maladjustments, overindividualism, inherited tendencies? How far is the community responsible with its failures in housing, recreation, and lack of concern for the essential needs of childhood? What influences arise from room congestion, low wages, exploitation in labor, or lack of religious training? These are fundamental questions, all of which merit concern in determining the causal elements of truancy, retardation, and elimination. If one summarizes the causes of truancy as due to physical abnormalities, mental defects, inefficient or degraded parenthood, various annoyances, and communal neglect, both the educator and the hygienist are interested in these unfavorable conditions; to correct them when found, and to raise familial standards so that they may not affect other children either at or preparing to enter school.

The problems of retardation undoubtedly involve a readjustment of our curricula, but even with an ideal course of study a relative degree of retardation will exist, not merely because of late entrance or unfamiliarity with English, but because of a variety of effects bound up in the personality of childhood, home conditions, social contacts, and physical and mental ineptitudes. The pedagogically retarded child, to a great extent, is the precursor to early elimination.

There is more or less confusion in our use of the words "normal child" and "average pupil." The average pupil may have to repeat a grade because of physical defects or disease, but this fact should not place him in the category of those who are retarded. The "normal child" is largely an abstract

concept. In point of fact, the "normal child" evidences many variations from physical, mental, and moral perfection. The term does serve, however, as the symbol of an idea of child power, partially determined by our knowledge of the "average child," as manifest in its physical growth, its mental progress, and its standards of behavior.

A large portion of retardation is concealed by reason of the tendency to force promotion, irrespective of the reasons responsible for inferior educability or delayed educational progress. The desire to bolster up school efficiency in terms of percentages of promotion is an obstacle to the fullest understanding of the causes underlying non-promotion. If, however, non-promotion were to be considered in the first four grades only, the elements of retardation might be reached earlier, and result in a higher degree of attention.

A study of backward children which I had made in 1914 indicated that irregular school attendance was not a large factor in retardation, nor was late entrance of unusual prominence. Only about 8 per cent. of the children were found physically normal, and a very high proportion evidenced a degree of mental dullness, including under this term those found actually to be mentally defective. One may ask, properly, if it is sufficient to account for retardation, that is, children two or three years or more over grade, on the basis of late entrance and slow progress caused by mental deficiency, backwardness, physical defects, illness, irregular attendance, change of school systems, environment, lack of application, lazy, etc. Do not these terms require further information? Why is there backwardness? Why irregular school attendance? What is wrong with the environment? Why is there lack of application? What is laziness?

In a report of the School Committee from Boston, out of 8,496 children, failing of promotion, 538 were characterized as lazy, 495 as inattentive, and 486 were charged to absence caused by truancy, and neglect of homework, while 2,803 were accounted for on the basis of mental immaturity. Certainly these proportions of children deserve more explanation than is afforded by the terms indicated. Are educators and doctors willing to accept such a terminology of explanation that fails to explain?

Newmeyer, in accounting for the causes of retardation, groups them under three heads, first, physical defects; second, home surroundings and environment; third, faulty educational methods and inexperienced teachers. In listing the causes of nonpromotion as an aid in detecting mental dullness, he employs the following classification:

Causes Due to School or Teacher

1. Faulty curriculum.
2. Lack of success of teacher.
3. Pupil and teacher incompatible.
4. Frequent absence of teacher.
5. Crowded classrooms.
6. Standard for promotion too high.
7. Change of teachers.

Causes Due to Pupil

1. Frequent change of school.
2. Truancy.
3. Irregular attendance.
4. Lack of interest.
5. Ignorance of the English language.
6. Slowness, dullness, inattention or idleness.
7. Mental defect.
8. Physical defect.

Causes Due to Home Conditions

1. Poverty, causing malnutrition and necessity of work after school.
2. Bad environment at home or with associates.
3. Home cares and responsibilities.
4. Carelessness of parents.
5. Lack of control causing incorrigibility.

I submit that this listing of causes, from the medical standpoint, is inadequate, and forces one back to a substratum upon which most of these alleged causes are founded. These again re-emphasize certain basic values to which insufficient thought and attention have been given. These derelictions, however, are not more common on the part of pedagogues than on the part of physicians interested in school administration.

While the elimination of children from school is partially accounted for by those who drop out because of ill health, and those who make slow progress because of unremedied though remediable defects, there are numerous other elements entering into the school defections that are not beyond correction. If the current judgment of elementary schools be sound, that an eight year course of study is the minimum of training required for an intelligent citizenship, the problem of elimination assumes particular importance. It is equally urgent that thought be focused upon the high degree of elimination during the adolescent period, when the unfolding nature of boys and girls yields a constant stream of undefinable emotions leading to new ambitions and aspirations alienating individual interest from tasks that are monotonous, ideas that are static, and the gross formalism of adult projects.

In an explanation of withdrawals of pupils from school, I find listed such terms as: to go to work; needed at home; poor health; physical defects; sickness in family; failure in studies; indifference; suspended or expelled. In one city the causes are listed as preventable and non-preventable. The preventable include: work and over compulsory age. The non-preventable, 83.5 per cent. moved out of the city, at parochial school, under compulsory age, death, sickness. In an interesting report of the New York High School Teachers' Association the reasons for leaving high school were grouped under these general heads: going to private school, personal illness, home conditions, going to work, moved from city, unknown reasons.

I am selecting certain reasons given by boys leaving one high school, and girls leaving a girl's high school as indicative of some interesting fields of work wherein medicine and education overlap. *The boys:* Desirous of financial independences, mental incapacity, especially for algebra; parents unsympathetic with school ideals; took course not fitted to ability; too large for class mates; discouraged by teachers; did not like it, too tame; too much home work; too great interest in the opposite sex. Illness was not given in a single instance. *The girls:* Course did not appeal; personal illness; worked too hard in school; wanted to go to work; too old; trouble with teacher; too lazy. In all probability these responses were not wholly genuine, but they may be taken for what they represent—the explanation of an educational delinquent for his own action—in all probability, the rationalization of an act motivated from the unconscious.

It is thus apparent that elimination from school carries with it many questions that a sanitarian

would bear in mind in scrutinizing reasons for a peculiar morbidity or mortality in any district of his community. It is patent that physical defects are not predominant factors, though they may be responsible for approximately 5 per cent. of elimination, 6 per cent. of non-promotion, and 7 or more per cent. of retardation. It may be that further study of those termed dull, inattentive, or lazy, would show them to be suffering from some physical defect of a remediable character.

It is almost bromidic to refer to the relation of health to school progress. In general, it has been stated that the better the health of the school child, the more rapid its progress. There is truth in the statement only if health connotes the complete health of the children, including the physical, mental and moral components. Health is not to be interpreted merely in terms of anatomy and physiology, but also involves psychology, and the ability to make essential adjustments. Illness, in one form or another, exclusive of physical defects, is probably one of the largest factors operating, accounting for nearly 25 per cent. of absences from school, 10 to 15 per cent. of the eliminations, 10 to 12 per cent. of non-promotion, and for at least 10 per cent. of retardation.

It becomes evident, therefore, that school progress possesses a large content for the hygienist. The investigation of pressure, over-study, competition and examinations for mental determinations has not been adequately defined. The forcing of standards in mass education is not to be deemed hygienic. The maladjustments in the personalities of teachers, the low standards of admission to the teaching profession, the lack of adequate knowledge concerning child psychology and physical growth operate against the finest type of hygienic school methods.

One may well bear in mind Spencer's note, "If, therefore, it is the duty of the State to protect the health of its subjects, it is its duty to see that all the conditions of health are fulfilled by them." This applies to the teachers, the subjects, and the objects taught. More and more, one appreciates the inadequacy of our interpretation of educational performance. The hygienist must deal with personal problems and their important manifestations, as must the teacher. Both must ask such questions as: Why is this child unruly? That a poor speller? Another deficient in arithmetic? Why is this one so frequently absent? That one a truant? The other delinquent? Which child has a visual defect? Which an aural? Why does this one fall asleep at his desk? That one talk without permission? etc. The mere ascertainment of a fact is negative in results. To know that a child is a truant conveys no message. To know that a child is myopic gives some promise of accomplishment. Knowledge that this one is thin, pale and underweight is valueless, unless the etiology is revealed. The readjustments that educational hygiene demands must be based upon knowledge concerning the methods of cure, as developed from an investigation of the fundamental factors causing the specific conditions interfering with education.

I admit that this requires a comprehensive analysis, with an understanding that education is not an element of civilization that is confined within the walls of a school. It requires the study of all

the factors entering into the life of school children. The problems evolve from the teachers, the principals, the school, the inherited nature of the child, his acquired physical state, his home relationships, his associates, recreations and social environment, age, racial character, and every other item that can bear a relation to the development of his individuality, and the direction of his character and potentials as demanded for school progress.

Thus, without any discussion of machinery or agencies to be employed, one may arrive at these conclusions as to the aims of educational hygiene. (1) It seeks to understand the optimum conditions conducive to the promotion of health and constant school progress. (2) While recognizing the insistent problems of the so-called abnormal child, it lays special stress upon living in and through the school for the benefit of the so-called normal child. (3) It searches for data indicating the correlation of educational defects with the underlying physical, mental, economic and social causes as far as may be determined in the light of our present knowledge. (4) It desires to arouse educational authorities to the importance of paying specific attention to the problems of hygiene in teaching. (5) It purposes to stimulate the study of healthful conditions in schools that make for better progress. (6) It essays to co-operate with teachers in investigating the worth of educational methods devised to correct slow progress through school. (7) It solicits an explanation of educational curricula in normal schools and colleges, training teachers, so that, as students of education, teachers will acquire sufficient basic information to qualify them to function as hygienists in schools, without assuming any of the responsibilities or duties of physicians or nurses. (8) It regards the teacher's function as educational and not medical, but considers the teacher as a natural aid in protecting and conserving the communal health by reason of her daily conduct with school children. (9) Its medical vigilance relates to hygiene that will serve to decrease retardation, elimination and truancy, so that the standard of education may be raised, and thereby enhance the efficiency of potential citizenship.

264 WEST SEVENTY-THIRD STREET.

A REVIEW OF THE MATERNAL MORTALITY ASSOCIATED WITH PREGNANCY AND LABOR IN THE BRONX DURING THE PAST TEN YEARS.*

BY A. J. RONGY, M.D., F.A.C.S.,

NEW YORK.

THE art as well as the science of medicine is inexact. The longer one is engaged in the practice of medicine the more one will realize that it is highly individualistic. The competency of a physician, as a general rule, will be in proportion to the quality of his mental faculties. To become expert in any branch of medicine requires close application and profound study of the subject at hand. One must not only be conversant with the modern trend of thought, but must also keep in touch with some of the correlating departments. He must not

*Read before the Bronx County Medical Society, November 17, 1920.

only be familiar with all the present methods, but he also must have some knowledge of what has been done in days gone by, and above all the man who is capable of selecting and applying any given procedure at any time to any given case is the man who is likely to make the least number of mistakes and will guess correctly the greatest number of times.

To decide properly one must be capable of clear thinking. In order to do that one must have sufficient rest. No human being can be continuously subjected to a constant strain and at the same time be expected to give what is best in him—such a routine never makes for efficiency.

The public must be made to realize that obstetrics is a disturbing specialty, continued practice of which will undermine the health of the strongest man, and unless the present system under which obstetrics is being practised is changed, good judgment on the part of either the physician or specialist can not prevail. The brain must become lazy when night work is superimposed after a strenuous day's work. That is why the mind of the average busy obstetrician is half the time befuddled. That is why very few obstetricians display real brilliancy in their work. Anyone who is willing to spend the greater part of his life in the antepartum room and listen to the moans and groans incident to the pangs of labor, will sooner or later become less wise than he was when he decided to embark upon that specialty.

It is, however, fortunate for the practice of obstetrics that it does not require great genius to carry out some of its details. A man with very ordinary ability who would make but a very mediocre physician or surgeon may—after a fashion—become a very able obstetrician in a very short time, for the problems nowadays are very simple—it is either to pull out or cut and the great feat is accomplished.

Obstetrics is the only branch of medicine which should be truly an art, for it is practically the only specialty which assumes a mathematical aspect, but it seems to me that, like figures in general, it does not always tell the true tale.

I have often wondered whether it is the fault of the modern woman or of modern obstetrics that normal labor is becoming less and less a thing of the past and if the present pace is kept up the time will soon come when a child who has conquered the art of obstetrics and been delivered spontaneously will be greeted as a hero.

Nowadays women do not deliver themselves—the children are brought into the world by methods. Some do it by version and when one reads the results of the chief advocate of this method it almost sounds like a fairy tale, but I know that every word he says is true. I did not believe it myself until I went, saw, and was conquered. The master hand of Potter has overcome one of the heretofore most dreaded complications associated with childbirth. He taught us how to do version properly. He plainly demonstrated that we are all wrong in the way we perform it.

Picture for a moment a man attending to over eleven hundred labor cases a year and consider that over 80 per cent. of the deliveries are accomplished by version and extraction, and it does not make

any difference to him whether it is the first or the tenth child.

Now when I opposed Potter's teaching on the floor at a meeting of the American Association of Obstetricians and Gynecologists, I was attacked by some of his friends who argued, "If Potter can do it, there is no reason why every other first class obstetrician should not be able to do the same thing." Theoretically, it should be so, but practically, it does not hold good. Potter is a master of his art and what he can now accomplish with his method of version, the average obstetrician will never be able to do. Therefore, I insist that version as a method of delivery is in the majority of cases still dangerous, and that in the hands of a man whose judgment of the case may not be very accurate and whose skill is not so good, it will not only work havoc with the mother, but it will cause many children to be still born. Version should be performed in selected cases only, specially so in primiparae.

Many obstetricians are more brutal and they resort to "cutting"—some cut above and others below. I do not know who does the greater damage. The objection that I have to it is that a great deal of it is unnecessary "cutting" and that every tyro in surgery undertakes it, and may it be said to the credit of the woman that she even seems to withstand the onslaught of modern obstetrics.

Now no one in his full senses will condemn cesarean section as a method of delivery. In properly selected cases it is a life-saving operation for both mother and child, but who can condone it when it is done as a "time-saving procedure" in simple cases of dystocia by men who are not able to judge properly? Cesarean section is not dangerous in its immediate results, but anyone who has performed section a second or third time on the same patient knows how often the uterus is surrounded by a mass of adhesions which cause a great deal of discomfort to the woman, particularly so during pregnancy. We must realize that, once a woman has a cesarean section, all her future pregnancies assume a pathological aspect, her chances to give birth to a child are normally less than 25 per cent., and furthermore there is always danger of rupture of the scar during subsequent pregnancies and labors. That this is so I pointed out some time ago and now it is the consensus of opinion that rupture of the scar does take place in fully 3 per cent. of cases.

In borderline cases cesarean section should never be performed unless the patient has had a fair test of labor—not at home, but in a hospital. I never hesitate to operate on hospital patients because they have been in labor for some time or because the membranes are ruptured. My only criterion in such cases is the pulse. If there is a change in the pulse rate one should be cautious.

Some make perineal incisions to hasten delivery or as some of the authors put it, "to save the pelvic floor." Some cut "sideways," others cut "midways." To my mind it does not make very much difference where you cut, because by the time you are ready to incise the perineum the damage to the urogenital septum is already done. The time to save the pelvic floor is before the head passes the bony outlet and this is best done by the "ironing-

cut method" of Potter. A laceration very seldom occurs if the perineum is properly ironed out, but what is still more important is that by this method the anterior vaginal wall and the tissue supporting the bladder are also saved.

During the hot spell last summer, I delivered most of my patients by forceps as soon as dilatation and retraction of the cervix was complete, and very seldom did I have to make any repair of the perineum, internally or externally, if the patients were properly prepared.

When and how to use forceps is to my mind the most important question in obstetrics, but unfortunately in my experience it is still a procedure which is adopted without the least forethought or knowledge. To hook on a pair of blades to a fetal head in the absence of full dilatation of the cervix or without knowing the exact position of the head, and pull with all your might and main is something that must be condemned. The damage done to the pelvic floor is very often irreparable, to say nothing of the many still born children which it causes.

Perhaps I have been especially unfortunate in that respect. I really would not dare to relate some of my experiences. I shall never forget one of those episodes. A III-para having been in labor twenty-four hours, the family physician decided to use forceps. He asked a colleague to give the anesthetic, but somehow he was unable to introduce the blades. He then called another friend, who succeeded in applying the forceps, and then the "pulling match" began. Hands were changed many times until finally after a great effort the strongest of the trio succeeded in breaking the table and the patient was thrown to the floor. At this stage I was called. I found the three physicians surrounded by a crowd of men and women, quite excited. They tried to unlock the forceps and remove them, but they were unable to do so. On examination I found that the left blade was hooked onto an ovarian cyst and was not in contact with the fetal head at all. I could go on recounting many similar incidents, but this is not my purpose just now. The point I wish to make is this: Given a case of labor which does not progress normally, a great deal more is at stake than is in some of the simple surgical conditions and yet in the one instance the attending physician assumes all responsibility, while in the other he refuses to carry the burden without some division of responsibility.

The one thing that must impress itself upon our minds is that the greatest amount of damage done is not by the use of forceps but by their premature use, before the head is fully rotated or before the cervix is fully dilated and that if only all of us would learn to substitute morphine for forceps during the first stage of labor many a woman would fare better. In a tedious first stage we must use morphine, give it once, give it twice, give it until the cervix is fully dilated.

In order to get a more intelligent understanding of the obstetrical situation, we undertook a study of the fatalities associated with the pregnancy and labor in the Bronx County because we believe that the physicians in this county, as a general average, are better prepared for the practice of medicine, as they consist of a group of men most of whom have some hospital training.

Right here I would say that the statistics of the health department are very incomplete for the purposes of medical investigation. Very little useful data can be obtained from the certificates filed with the department except a few general items. I feel that the birth certificates, instead of having the law governing vital statistics printed on the back, should have a few medical items about the mother and child. Such as presentation, instrumentation, duration of labor, eclampsia, placenta previa. It could all be put on the back of the same certificate so that it would not disturb the present method of the filing of records of the Health Department. Such certificates would give us some clue as to the kind of obstetrics which is practised. A study of such records would bring forth some valuable deductions and conclusions. In addition, all cases of post-partum infection must be made reportable by law. This would enable us to have some idea of the morbidity due to infections. It is a pity that such an enormous amount of useful information is lost to the profession as well as to the public year in and year out.

Now let us see what we have actually learned. I was startled, to say the least, to find that in every 1,000 deaths from all causes 7.3 were due to childbirth, and if we include sepsis, due to abortion, it was 8.9, almost twice as high as the maternal mortality of the entire British Isles, which is 4.2 per thousand deaths, and the highest they have in any district (North and South Wales) is only 6.3. If the mortality was so high I wonder what the morbidity was! There must be something wrong somewhere. I have an idea where the remedy lies, but shall defer discussion of it for some future date. I shall content myself for the present by pointing out a few of the more striking items and call attention to the more common complications associated with pregnancy and labor which I think could have been prevented to some extent.

Every medical student is impressed with the fact that there is a definite pre-eclamptic stage and any intelligent physician, if he will only take the trouble to find out, has the means at his command to ascertain the extent of any toxemia occurring in the latter months of pregnancy, and when it assumes a dangerous aspect. Were the pregnant women carefully watched, when we find that one hundred and fifty patients died as a result of eclampsia? The mortality of eclampsia is variously estimated to be from 15 to 33 per cent. Tarnier places it at 30 per cent., Lohlein at 19 per cent. Figuring the mortality rate on a basis of 20 per cent., we accordingly had during the past ten years over eight hundred cases of eclampsia in this country. What a mockery is the teaching of our medical schools and hospitals!

Who is at fault? I admit that in many instances the patients are to be blamed, for some of them are too ignorant to realize the benefits which may accrue from proper medical supervision, but on the whole the responsibility for eclampsia rests with the physician. Occasionally one may encounter a case of eclampsia which occurs very suddenly with no premonitory symptoms. However, the greatest number of cases have a definite pre-eclamptic stage lasting anywhere from seven to twenty days, and if proper treatment is then instituted, severe toxic

symptoms will be prevented in almost all of the cases. A patient who develops signs or symptoms of toxemia as evidenced by change in the blood pressure, epigastric distress, or pain, general malaise, and persistent headache, should be placed in a hospital for observation, and if, under proper treatment, she does not show a tendency to improve, labor should be induced, because the explosion may be sudden and may result fatally. The method of inducing labor is very simple, a large rectal tube is introduced into the uterus and is followed by cervical and vaginal packing with plain gauze. Labor pains will set in anywhere from three to thirty-six hours. They are sure to happen. I always use the rectal tube, it has never failed me but once, when I had to introduce another tube at the end of forty-eight hours. It is simpler than any of the other methods. It is easier of execution and the patient does not have to be confined to bed during labor. The only precaution which must be taken is not to rupture the membranes, but if care be taken that the tube hugs the uterine wall, it will not happen. In primiparæ primary anesthesia is given, in multiparæ no anesthesia is necessary.

In recent years the treatment of eclampsia has undergone a radical change. As is well known there were always two schools advocating different methods of treatment for eclampsia. Until a few years ago the radical method as advocated in this country by Peterson and his followers prevailed. However, a close scrutiny of their statistics failed to show that the maternal mortality was materially reduced. So the pendulum swung in the conservative direction and I fear it swung too far. Personally, I never adhered to any dictum in medicine. Each case must be studied and treated individually—hence I may be conservative in my treatment of one patient and very radical in another. All depends upon the degree of toxemia that is present at a given time. Patients who have long intervals between convulsive seizures and who regain consciousness after the attack is over and in whom the kidneys are not entirely blocked, are favorable cases for the conservative plan of treatment. Such patients should be morphinized to the limit and labor should be induced at the same time. If, however, the convulsions are severe, the intervals between attacks short, and the patients are stuporous or unconscious and no urine is obtained from the bladder, such a clinical picture calls for immediate emptying, and the quickest way to accomplish it is by the abdominal cesarean section. No time must be lost in these cases, the toxic explosion is too great, the system is overwhelmed, and delay may prove fatal.

During the last two years 309 women died in this county from sepsis following pregnancy; 169 died of post-partum sepsis and 140 of post-abortion sepsis. It seems to me that the true story is told in the fatalities following abortion. During my twenty years of active hospital work, having had an unusual opportunity to observe a large number of cases, I never saw a case develop sepsis in whom an abortion had been performed. Now all patients upon whom an abortion is performed in a reputable hospital usually have a definite medical indication for the interruption of pregnancy. It is always a

constitutional condition, of either an organic or a metabolic nature. The resistance in such cases is very much diminished and the women are therefore more prone to infection, still they pass through the ordeal well and but seldom develop complications. Why then do patients upon whom abortions are performed outside of hospitals develop so many complications? No great stretch of the imagination is required for the answer. Incompetency and uncleanness is the combination which has led many a woman to her grave. It is unfortunate that

probably the same is true to a large extent in cases of post-partum sepsis. Somehow asepsis or antisepsis is not stringently adhered to in many cases of labor. All of us have periods of lapses in our technique, particularly when we have had no mishap for some time, but I believe that that is not the main cause for the many infections which take place in the lying-in chamber. To my mind, and I feel that I speak from experience, for I have seen as many as six cases of post-partum infection in twenty-four hours, the cause, as a rule, is either

too early interference on the part of the attending physician, or the unusual conservatism on the part of many midwives who permit their patients to pass through a tedious and prolonged labor which leads to exhaustion and infection in not a few of their patients.

Too early interference during labor, when the cervix is not fully dilated and when the head is not well moulded, must lead to very extensive traumatism of the genital tract. The lacerations are usually irregular and as a result the tissues become devitalized. Traumatism is the most important of all the predisposing causes of infection, especially in patients who have had prolonged and tedious labors. It is almost unbelievable that 21.5 per cent. of the fatal cases associated with childbirth were due to sepsis, but unfortunately it is true. All of us cannot but feel that a goodly number of these patients should have been managed differently. I say so advisedly because I saw at least 30 per cent. of all the fatal post-partum cases which occurred in this county during the past ten years. Often have I felt that the women did not get a square deal.

The study of the fetal mortality is also not very encouraging; incomplete as the data are, still one cannot but think that there is a great lack of knowledge on the part of the medical profession concerning the physiology and pathology of pregnancy. It does seem a great waste on the part of nature that 8.6 per cent. of all pregnancies come to naught. It is certainly a great loss to the nation. An analysis of the statistics shows that the percentage of still births, viable and non-viable in relation to the total number of births was 6.6, and that the percentage of infants who died within thirty days was two, also that the total fetal mortality was about 11 per cent.

A careful study of the statistics, incomplete as they are, convinced me more than ever that the percentage system of the practice of medicine, particularly as it relates to obstetrics, is not only inadequate, but in all fairness to the physician and in justice to the woman, it must be improved if not changed. Obstetrics will never reach a high level of efficiency as long as the general practitioner is compelled to accept maternity cases to eke out a livelihood from his profession; and no sooner does he acquire a fair practice than the first thing he discards to the ash-heap is obstetrical work. No man can be ambitious to become an expert in a field of work which he hopes to give up as soon as conditions permit; such a mental attitude is not conducive to good work.

I do not know who is responsible for the ridiculously low fees which physicians are charging for obstetrical work. It seems to me that the time and effort spent by the attending physician on the simplest labor case is greater than that of the surgeon in the most serious surgical conditions. Still the public will pay to the one and refuse to give a fair compensation to the other. It is astonishing that neither the public nor the physicians realize that good services cannot be obtained under such circumstances. Child-bearing and child-rearing constitute a very important industry. Do we give it the attention it deserves? Judging from the experience in the past, I fear that man will never solve this question for the woman. This is obviously a woman's problem. They suffer the consequences of all its shortcomings. The women, instead of wasting their time in becoming petty politicians or social reformers, should primarily interest themselves in the most vital questions concerning their welfare. It is their duty to see to it that the practice of obstetrics is

removed from the sphere of general practice. They should see to it that physicians who decide to choose obstetrics as their life work are adequately paid for their services, so that they should not be compelled to seek other practice. The women must realize that the average home is not conducive to good obstetrical work, especially should a complication arise. They should make every effort to build maternity homes—not of a charitable character—throughout the county and place them in charge of competent physicians whose duty it should be to see that every woman is carefully observed during pregnancy, and properly attended to during labor.

If the women will only learn primarily to look after their own interests and concentrate all their efforts toward the improvement of their own physical well-being and make childbirth safer for themselves, then and then only, will the practice of obstetrics reach the high level of efficiency it deserves. Then only will its practice be considered a pleasure instead of a drudge and annoyance to the obstetrician as well as to the general practitioner.

In conclusion, I wish to express my appreciation of the painstaking efforts of Dr. Samuel Rosenfeld and Dr. Milton Goodfriend, in collecting all the data forming the basis of this paper, from the Health Department of the City of New York.

345 WEST EIGHTY-EIGHTH STREET.

THE VALUE OF PEDOGRAPHS IN RECORDING AND DIAGNOSING ABNORMAL FOOT CONDITIONS IN CHILDREN.*

BY JACOB GROSSMAN, M.D.,

NEW YORK.

CHIEF OF THE ORTHOPEDIC CLINIC, LEBANON HOSPITAL; CHIEF OF THE ORTHOPEDIC CLINIC, STUYVESANT POLYCLINIC; INSTRUCTOR OF ORTHOPEDICS, NEW YORK POST-GRADUATE MEDICAL SCHOOL.

THE diagnosis of weak feet in both children and adults is made in the majority of instances by inspection. Occasionally walking or hopping tests and palpation may be used in addition. These methods are sufficient to give us a mental picture, which for the time being may enable us to make the diagnosis. We have no means at the present time of comparing these findings with those presented six months later, should the parent return to us for an opinion of his child's condition. We cannot say with any degree of accuracy whether the patient's condition has improved, remained stationary, or become worse. By means of properly made pedographs, we have a photographic reproduction of the condition of the patient from the initial visit, with which subsequent pedographs, taken at any time, can be compared. Hence we have at our disposal a means whereby we can accurately tell the patient what has occurred as the result of our treatment.

By the pedograph method five prominent signs are taken into consideration: (1) The pedograph picture; (2) the contour line of the foot; (3) the height of the scaphoid bone; (4) the muscular development of the soles of the foot, especially those

under the arch of the foot; (5) the presence or absence of the juvenile fat pad.

In taking the imprint the individual is seated, the leg is extended and the bare foot is painted with an iron solution. The foot is then hastily placed on

FIG. 1.—Skeleton of the foot, showing the Feiss line, A-B.

blotting paper and the individual is told to place all the weight on that foot. At this point the contour line is drawn by using a pencil or pen held at right angles to the plane surface. This contour line demonstrates the amount of inversion of the ankle, or eversion of the heels and heel cords. The muscular development of the soles of the feet should be taken into consideration, as often a heavy bulging muscular layer will produce the picture of inversion of the ankle. The foot is then removed from the blotter and the height of the scaphoid bone is estimated. This is done by drawing a line from the posterior inferior aspect of the internal malleolus to the first metatarsophalangeal joint on its plantar aspect. (Figure 1.) The scaphoid in the normal adult foot is usually found one-half inch below this line. In children it varies with age. In the subsequent summary the average distance of the scaphoid below the line will be noted. The sole of the foot is then palpated and the muscular development noted as poor, fair, or good. The presence of the juvenile fat pad is also sought for.

A solution of tannic acid is now applied to the

FIG. 2.—Imprint of normal foot

iron imprint of the foot which turns a jet black, giving us a record which can be preserved indefinitely.

The base lines and the auxiliary lines are now drawn on the pedograph for estimation of the de-

*Paper read at a meeting of the Alumni Society of Lebanon Hospital, January 11, 1921.

formity should one be present. The first base line is drawn from a point posterior to the internal malleolus to the first metatarsophalangeal joint. The contour line extending beyond this shows the degree of inversion of the ankle or eversion of the heels and heel cords. The line of axis weight bearing is next drawn, from the center of the heel to a point midway between the first and second toes. A line is next drawn at right angles to the line of axis weight bearing from a point posterior to the heel.

FIG. 3.—Second degree weak foot.

Another line is drawn also at right angles to the line of axis weight bearing, from the first metatarsophalangeal joint. Midway between the last two lines, also at right angles to the line of axis weight bearing, is drawn the line of estimation. The line of estimation is then checked. One check is placed at the outer border of the imprint, the other check being placed at the junction of the line of estimation and the first base line, or if valgus be present, at the junction of the line of estimation and the

contour line. Midway between the two check marks of the line of estimation is the normal point. To the inner side of this point the line is divided into three parts representing the degrees of weak feet, while to the outer side of the point the line is also divided into three parts representing the degrees of pes cavus.

The use of pedographs in diagnosing and recording weak feet is by no means new. It has been advocated by Rice of Washington, D. C., and used extensively in the marine corps by Mann and Folsom. However, it has not, as far as I have been able to learn, been used in children.

With the hope of standardizing the findings in children one hundred children who were assumed to have normal feet have been pedographed. These children were selected because they had no symptoms referable to foot disturbances. The age of the youngest child was two years and the oldest thirteen. Several were chosen in each year between these limits. From the study of these cases the following facts have been evolved:

1. Up to four years of age, with few exceptions, the pedograph picture is of no value, as the juvenile fat pad, which is invariably present, always gives a flat impression as found in the third degree weak foot. This flat impression does not represent any pathological change, as it is not due to a flattening of the bony arch. This has been proven by frozen sections of the foot, which have demonstrated that the bony arch is normal and the hollow of it is filled by a pad of fat. However the height of the scaphoid bone, the condition of the musculature, and the fat pad can be determined in these cases. The average distance below the Feiss line for children of these ages was one-eighth of an inch for children two years of age and one-quarter of an inch for those three and four years of age.

2. The average distance of the scaphoid below

the Feiss line in normal children five years of age was one-quarter of an inch. For children six, seven, eight, and nine years of age, it was found to be three-eighths of an inch. For children ten, eleven, twelve, and thirteen years of age, it was found to

FIG. 4.—Second degree pes cavus.

be half an inch. As a rule variations from these averages indicated abnormal feet.

3. The muscular development was fair in nineteen and good in eighty-one cases. In the former cases weak feet were invariably present.

4. The pedograph was normal bilaterally in forty-two cases and unilaterally in thirteen cases. It was abnormal bilaterally in forty-five cases, thirty-three showing weak feet and twelve showing pes cavus. Of the former eleven were apparent weak feet, the weak foot impression being due to the juvenile fat pad, and twenty-two were pathological weak feet. Of the thirteen unilateral cases, nine showed weak feet and four showed pes cavus. The weak feet and the pes cavus deformities varied from one-half to three degrees. In weak feet the scaphoid was further below the Feiss line and in pes cavus was further above than in the normal foot.

5. The fat pad was especially marked in children up to four years of age. In many of these children

FIG. 5.—Third degree pes cavus.

it was responsible for the flat impression present.

Summary and Conclusions.—1. The analysis of one hundred children disclosed that more than one-half of what were assumed to be normal feet were abnormal.

2. Pedographs should be made on all school children, so that pathological foot conditions can be detected early and prophylactic measures instituted, where necessary.

3. Pedographs will prove useful in recording and diagnosing abnormal foot conditions. They also give us a photographic reproduction of the initial abnormal foot conditions with which subsequent pedographs can always be compared. They aid us in giving an accurate opinion about the patient's condition.

4. This method of recording and diagnosing abnormal foot conditions may not be infallible, yet in it we undoubtedly have the foundation upon which we can accurately study successive changes in the foot.

1182 JACKSON AVENUE.

A TOURNIQUET FOR ARSPHENAMINE INJECTIONS.

BY GEORGE EDWARD BARNES, B.A., M.D..

HERKIMER, N. Y.

So far as I am aware there is not on the market a satisfactory arm tourniquet for use in the administration of arspfenamine and nearsphenamine. The ordinary piece of rubber tubing so generally used cannot be adjusted with accuracy, and the tourniquets made especially for this purpose have serious objections.

I have devised a tourniquet that works almost ideally, being easily, quickly, and accurately adjusted and quickly and smoothly loosened. It consists of a strap which passes around the arm and through the ends of a block of wood, and of a wedge which is inserted between the block and the strap to produce any degree of constriction desired. It can be made by any carpenter, cabinet maker, or doctor who has the tools.

The block and wedge are made of hickory about five-eighths of an inch thick.

The block is two by one and one-fourth inches, and in each end of it is a notch just a little wider than the strap and sufficiently deep to allow the strap to play through it easily. Around the whole block, a little nearer to the surface which is to rest on the arm, is fitted a strong steel wire, the ends of which are twisted together on one side of the block, cut off and smoothed off with a file. This wire passes over the notches and forms pulleys through which the strap acts.

The wedge has a short side of one and three-fourths inches, a base of four and a half inches, and an hypotenuse of four and three-fourths inches, but the two latter sides meet, not at a point, but in such a way that there is formed between them a very short end of about one-half inch. This end is beveled on the flat, the edge being made quite thin. However, if preferred, the wedge need not have this blunt end, but may be prolonged to an acute point without a bevel on the side.

Fig. 1.

Fig. 2.

The block and wedge may be fastened together by a string passed under the wire on the former and tied around a small screw on the latter.

Any strap of suitable size having a buckle that catches at any point on the strap may be used. A very good strap of woven material can be gotten at most 5-and-10-cent stores. A good width is one-half inch. One should have several straps, so that in case of soiling a clean one will be at hand. (Rubber straps pull and pinch the skin.)

The tourniquet is applied as follows: The strap is threaded through both holes in the block, so that it passes over its upper surface, the two loose ends hanging below, the end with the buckle being just below the block. The block is placed on the upper surface of the arm at the in-

sertion of the deltoid, the longer end of the strap is passed around the arm and through the buckle and is drawn up only so that it rests loosely on the skin. The beveled end of the wedge is inserted between the top of the block and the strap, is turned so that its base rests on the block, and is pushed forward until the constriction is exactly as desired. The upper surface of the block and the two long sides of the wedge should not be much polished lest the wedge slip backward under the pressure of the strap.

The flat block is sufficiently long to project beyond the convex surface of the arm, so that, as the strap is tightened, the skin will not be drawn up against the ends of the block by the strap and pinched. The thickness of the block so raises the wedge that the point of the latter does not dig into the deltoid region.

As soon as the needle is inserted into the vein the tourniquet is loosened by gently pulling the wedge out from under the strap. This can be done without any disturbance whatever. Indeed, the withdrawal of the wedge is so simple that in case of some calm patients the doctor may insert the wedge from the upper or shoulder side and the patient can, when requested, quietly pull it out himself.

This tourniquet increases the facility with which a doctor, without the presence of an assistant, can administer arsphenamine in his office.

A CONCEPT OF X-RAY PATHOLOGY.

XII. GASTROPATHIES.

By A. J. PACINI, M.D..

WASHINGTON, D. C.

CHIEF OF LABORATORY AND X-RAY SECTION, HOSPITAL DIVISION,
U. S. PUBLIC HEALTH SERVICE.

THERE are four purposes in the technique of the x-ray examination of the stomach. These are to study (1) the residue, (2) the sediment, (3) morphology, and (4) motility. In the x-ray study of the stomach the first essential is to decide upon a "standard" technique. By standard is meant that uniformity be adopted in the question of selecting the proper contrast mixture, that the method of preliminary preparation on the part of the patient be similar in all cases, that the time interval be-

tween the successive examinations be fixed, and that every patient examined receives as nearly as possible a survey in every way identical to other patients. Obviously, every x-ray man is in the position to devise his own standard gastroenteric routine; but if the results of various operators are to be correlated it is manifest that there should be agreement in the basic methods employed in reaching the results. It is not the purpose to discuss the many methods in use for arriving at conclusions relative to the x-ray pathology of the stomach. Only one method will be propounded.

Preparation for the Examination.—The patient refrains from the evening meal and, before retiring, a soapuds enema is administered. It is best that all medication be stopped before initiating whatever preparation. The examination is begun for convenience with the motility test. Early on the morning of the examination the patient is given 400 grams of cooked cereal, preferably cream of wheat, to which has been added 80 grams of barium sulphate. The important constant of the motility test meal is that the proportion between contrast salt and carbohydrate be as one is to five, or 20 per cent. of contrast salt. In the study of the stomach and intestines the contrast salt had best be barium sulphate. (In the study of the esophagus bismuth subcarbonate is better than barium sulphate. The choice of barium sulphate for gastropathy study lies in the fact that barium sulphate is more quickly emptied from the stomach than is bismuth subcarbonate; so that six-hour retention when barium sulphate is used is more likely indicative of pathology than six-hour retention when bismuth subcarbonate is used.)

Six hours after ingestion of the meal a 14 x 17 plate or film is made in vertical posture and dorso-ventral exposure.

On the plate thus produced one studies first whether or not any residue remains in the stomach six hours after ingestion. It is perhaps best that the residue be reported in terms of percentage of the total meal. The estimate is roughly made and may be 0, 25, 50, 75, or 100 per cent. residue. It was Haudek who explained particularly why six hours was the time limit selected as a dividing line between normal and delayed emptying. Ordinarily a normal stomach will drive out the carbohydrate contrast meal (Rieder meal) in three hours; but a delay up to five or six hours might result from purely physiological causes. Rest and movement, psychic factors, eating or drinking after ingestion of the meal may all subscribe to a physiological delay in the emptying time. Oftentimes, even after six hours, a trace of residue remains in the stomach. When the residue is less than 5 per cent. factors conducive to delayed emptying other than pathologic should be sought. Residues amounting up to 25 per cent. may be due to pathologic changes and also to hypomotility, hyperacidity, or elongated hubhöhe. Residues up to 50 per cent. are most always due to pyloric obstruction owing to organic stenosis or spasm from ulcer.

The motility test, as pointed out by Haudek, rests not alone on the presence or absence of stomach residue, but also on the position of the "head" of the six-hour meal. Normally the head should reach the region of the cecum; but in hypermotility it

may be visualized far advanced into the large intestine, or in hypomotility it may be seen held back into the small intestine.

Disturbances of Motility.—Disturbed motility may, therefore, be revealed either as hypomotility or as hypermotility.

Hypomotility is evidenced by the presence in the stomach of an opaque residue which is to be studied for its size, location, and shape. An amount of residue approximating an area of one square inch is not important as a sign of pathology and may be explained by factors bordering on psychic control. A small residue varying from two square inches to 25 per cent. of the total meal is usually not expelled until twelve hours, and is rarely found without pathologic changes in the gastric mucosa. A medium residue may represent one-half of the original volume of the test meal and usually requires eighteen or more hours for its complete expulsion. It is generally the result of pathology incident to pyloric or lesser curvature, ulcer, or new growth.

The residue, if more than 50 per cent., is considered large and may at times consist of the entire meal, the final expulsion time varying from twenty-four hours to several days. A residue of this magnitude is invariably indicative of pathology.

Having estimated and expressed the size of the residue, its location should then be described. The location should be expressed with reference to two axes, one the vertical median line of the abdomen, the other the horizontal line joining the iliac crests. When the shadow lies to the left of the median line it indicates an approach to normal gastric tone, greater normality being indicated in an amount proportional to the leftward extension of the shadow; and when the residue lies to the right gastric atony and dilatation are suggested. In relation to the transiliac plane, hypertony is indicated in proportion as the position of the residue presents above, and hypotony in proportion as the position presents below.

The residue may lie on both sides of the vertical line when it indicates, most often, uncompensated pyloric stenosis usually resulting from pyloric obstruction of long standing. The shadow extends beyond the median line practically in proportion to the chronicity of the ulcer.

There may present a fragment of barium opacity to the left of the median line, its isolation and location suggesting retention of contrast mixture in an ulcer crevice. When the isolated fragment is found on the right of the median line it should suggest duodenal irritation.

When the opacity is associated with an ulcer situated on the lesser curvature, it lies, generally, to the left. Sometimes the residue may show a smooth outline lying with its vertical axis to the left of the median plane. The presence of a residue of this character should incite a careful survey along the lesser curvature with the view to determining the possibility of ulcer.

Having determined the size and the location of the opacity, one then summarizes the shape. It may be irregular, owing to the conformity of the unsmooth ulcer niche. An oval shape suggests a mold of a portion of the stomach contour usually near the pyloric end. In the deepest portion of an atonic stomach there may remain a residue of cre-

scient shape. In cancer of the pylorus the residue is usually rounded and markedly ridged at that part toward the pylorus. On the question of the significance of motility test residues Hirsch says:

Though a large residue has considerable significance without the consideration of any other factor, still it is important to think of it not by itself, but in relation to tone and peristalsis, pyloric morphology, etc. An increased vis a tergo applied to the passenger (meal) may push it through a narrowed passage (pylorus).

The small residue is found in compensated pyloric stenosis and duodenal disease. Adhesions do not produce a residue unless the adhesions be due to an ulceration.

Such a residue as is given in either of the last two groups is absolutely pathological of pyloric obstruction, due either to organic stenosis or spasm.

Atony and ptosis rarely produce a residue. If present, it is usually minimal and is with ease differentiated from a residue due to organic changes by the consideration of the other factors concerned in the motor functions of the stomach, the tone and peristalsis, both of which are diminished in atony and increased in early stages of ulcers. In the later stages of ulcer, however, the atony and dilatation of uncompensated pyloric stenosis is to be differentiated from the partly functional atony by noting that in the organic atony the residue lies in the median line and the pylorus is usually displaced considerably to the right, while in the latter the residue, if present, is smaller, lies to the left of the median line and the pylorus is usually in the median line below the level of the umbilicus. Then, too, the examination in the left lateral position or with the pelvis raised will cause expulsion of the residue through the pylorus. It cannot be denied, however, that with more attention to the proper preparation of the meal and the various details attending its administration the residue in pure atony will not often be found.

Even a minimal residue in a stomach exhibiting excessive tone and excessive peristalsis has a characteristic significance—an organic lesion—while the same residue in a subtonic or ptosed stomach, with feeble peristalsis and high acidity, may be explainable on the basis of functional causes or muscular insufficiency. Again, a scirrhus infiltration of the pylorus may exist and yet, because of pyloric incompetency, the stomach may be empty in three hours. To find a residue of one-eighth of the gastric content, with normal peristalsis, tone, a morphologically normal stomach need not indicate an ulceration or obstructive lesion; but such a residue with evidence of hypertony and excessive peristalsis, though in a morphologically normal stomach, means a pyloric spasm or obstruction. Thus hyperperistalsis and hypertony with high acidity and suggestive clinical evidence would, even if the emptying time is normal, demand a reexamination before the lapse of six hours. By itself, therefore, though giving the key to the examination, the residue, except as indicating gross pyloric stenosis, has no pathognomonic significance.

On the other hand, the stomach may be empty, but the position of the bismuth mass in the intestine, duodenum, jejunum, or ileum may indicate a hypermotility and lead to the inference that there is a gastric hypomotility. The actual emptying time must then be determined by repeated tests.

Hypermotility should be studied in relation to the tone, to peristalsis, and to pyloric patency. It is most usually the result of excessive tone reflexly produced from lesions of an irritating character in the ileocecal, duodenal, gall-bladder, and hepatopancreatic regions. Excessive peristalsis is increased in inverse proportion to pyloric stenosis; it being excessive when stenosis is absent.

A careful survey of the motility through the use of the Rieder meal is then followed by the sedimentation test, which is directed to a study of the stomach relative to its tone, niche, antral activity, and pyloric patency.

Sedimentation Test.—The contrast sediment salt consists of one ounce of barium sulphate stirred into four ounces of water. The examination is conducted during and immediately following ingestion. The posture is vertical, then right lateral and horizontal if necessary. After palpation under the screen a dorsoventral exposure may be made.

The method by which the stomach is filled may offer important clues to the x-rayist. Food entering the stomach must make room for itself in a potential space. As it enters the pouch it first lodges just below the cardiac orifice, generally assuming a V shape, the air-filled fundus showing above as a radiopaque bubble called the "magenblase." As more food enters, the potential stomach space is canalized and is shown as a vertical column from the cardiac orifice to the region of the umbilicus. As more food enters, the column curves to the left (patient's right) and becomes everywhere broader until finally the entire organ is distended in proportion to the amount of food taken.

If the stomach contains secretion the sediment contrast mixture may drop from the esophagus to the fluid level and then rapidly gravitate to the deepest portion of the viscus. Very shortly after administration the barium deposits in the most dependent parts of the stomach, according to the position of the patient. Irregularities in the continuity of the mucus membrane produced by an ulcer-bearing area, or diverticulum, or niche will be shown as various degrees of puckering and pouting in the form assumed by the barium deposit. The sediment mixture may be spread over any part of the wall of the stomach by proper palpation, and minute studies of the irregularity of surface of any area can be obtained with an intimate accuracy approached by no other method.

In speaking of the tone of the stomach the x-rayist means the property possessed by that organ of keeping its contents in tubular form. This tubular form is manifested as well with five ounces of fluid mixture as with fifteen ounces. On the basis of tone, peristalsis becomes manifest. Peristalsis and tone are intimately associated and bear a practically simultaneous relation.

Antral activity is early observed, inasmuch as the water of the sediment test is quickly expelled from the stomach. Pyloric patency and pyloric morphology are readily studied, as the barium is shaped by the parts that contain it at the pyloric orifice.

After a study of the residue and the sediment, the third part of the examination, or study of the morphology, is begun. The meal is barium sulphate, three ounces, in buttermilk, one pint. The examination is begun directly after ingestion. The patient is posed vertically and horizontally and either at the end of inspiration or expiration. For studies in duodenal mobility exposures made before and after inspiration are valuable in deciding the fixity of the duodenal cap. The exposure should be dorsoventral. In the study of the morphology one examines for the type, size, axis, position, outline, mobility, and peristalsis of the stomach and for the type, size, outline, mobility, and peristalsis of the duodenum. Before proceeding with the discussion of the variations incident to pathology it may be well to include a discussion of the "normal" stomach.

The Normal Stomach.—The stomach may be divided into a proximal middle and distal third. The proximal third is known among some roentgenologists as the *pars cardiaca*, the middle third as the *pars media*, and the distal third as the *pars pylorica*. At the junction of the esophagus and the stomach there is an incisure called *incisura cardiaca*. On the lesser curvature just distal to the junction of the middle and distal third there is usually an incisure commonly called *incisura angularis*. The pylorus is separated from the stomach by the *pyloric sphincter* or *incisura pylorica*. The stomach is never completely filled with liquid; and in its upper part air and gases collect, appearing on the plate as a radiolucent area bounded above by the curved limit of distended stomach wall and below by the horizontal fluid level. The space included between these boundaries is the gas bubble or "magenblase." Haudek applied the name "hubbone" to that portion of the *pars pylorica* represented by the height of the pyloric opening above the lowest point on the greater curvature.

According to the habitus of the individual a stomach may normally be hypersthenic, sthenic, hyposthenic, and asthenic. If the type of the stomach conforms to the habitus of the individual it is said to be orthotonic; but when it does not so conform it may present excessive tone—hypertonicity; diminished tone—hypotonicity; absent tone—atonicity. In a case of asthenic stomach the orthotonicity may, as a result of persistent pyloric stenosis, be changed to atonicity. In x-ray pathology the type of the stomach should be recorded and also the habitus of the individual. It should invite suspicion to meet with a stomach type which is contrary to that normally expected for a given individual habitus.

The size of the stomach is a matter that admits of no mathematical precision. It is sufficient simply to state that the organ appears of normal size, or small, or large. Someone has given the dimensions of a normal stomach as being 12 inches long; 5 inches wide, and the walls a fifth of an inch thick, with a capacity of 40 ounces; but it is well to remember that the stomach is, after all, a potential cavity that may be small under certain conditions and, under others, very large.

The axis of the stomach is virtually a description of the long diameter which may be vertical, oblique, or horizontal.

Factors that determine the position of the stomach are the habitus of the patient, the tone of the stomach, abdominal wall musculature, the position of the adjoining organs, and the condition of the filling of the underlying intestine. The position is described; for the *pars cardiaca*, with relation to the diaphragm; for the greater and lesser curvatures, with relation to the intraspinal line and median line; for the *pars pylorica*, the relation to the ordinate axes is also adequate.

The outline is everywhere smooth and is indented by certain normal incisures that appear at regularly occurring places.

Peristalsis is visualized under the screen as ring-like constrictions that encircle the stomach and progress from the fundus to the pylorus, becoming more accentuated and pronounced as the pyloric antrum is approached. It is impossible to prescribe

any cycle of events that is characteristic for any and all stomachs; nor is it advisable to complicate x-ray pathology of the stomach by introducing in connection with the study of peristalsis the conception of gastric cycles, each with their systoles and diastoles. It is only necessary to observe the peristalsis and, if it is even and regular, so to remark; but if it presents obvious irregularity and accentuation, merely to describe the abnormality discerned.

The Normal Duodenum.—There are two portions of the duodenum that invite x-ray interest: the bulbous portion and the villous portion. The bulbous portion is embryologically related to the stomach and should not, indeed, be studied as a separate anatomical unit, but rather as a physiological part of the stomach.

The bulbous duodenum (or stomach cap of Cole) may present a triangular, spherical, or irregular type. Its position is stated in terms of relation to the pylorus. Its size is recorded as normal, small, large, or indeterminate.

A study of the outline should include a description of incisures, defects, or niches. Their location and number are described, as well as the size and form (deep, shallow, smooth, irregular).

The evacuation of the opaque meal is studied in terms of completeness (complete or incomplete) and rate (rapid and slow).

The villous portion of the duodenum is pathologically related more nearly to conditions affecting the small intestine than to conditions affecting the large intestine; it will be discussed, therefore, under the title of "enteropathy."

(To be continued.)

SOME OBSERVATIONS ON DEMENTIA PRÆCOX.

By J. T. A. WRIGHT, Ph.G., M.D.,
AMITYVILLE, N. Y.

FORMERLY RESIDENT PHYSICIAN OF RIVERLAWN SANITARIUM;
ASSISTANT PHYSICIAN, ALLEGHENY HOSPITAL FOR INSANE, ETC.

PSYCHIATRISTS at the present time are investigating, studying, and paying more attention to this disease, perhaps, than to any other in the whole domain of psychiatry, and I may say, are obtaining more curable results—thanks to the attention paid to the causative relationship of focal infection, led by Dr. Cotton of Trenton, and to investigation in other directions, particularly in endocrinology.

To arrive at the cause or causes of this malady is the prime desideratum, of course; then treatment along strictly scientific lines may be instituted, instead of the waiting, do-nothing policy followed by so many institutions at the present time. Experimentation, within certain limits, is justifiable in the attempt to find the real etiology and cure of a disease which particularly strikes down the young and promising, and which furnishes probably forty per cent. of the inmates of hospitals for the insane.

The pathological pictures shown in the works of Kraepelin, White, Peterson, and others, with the degenerative changes which have taken place in the nerve cells and fibrils of the cortex, are hardly thought to be due to germicidal action *per se*, but rather to disturbance of nutrition, and to the direct irritative action of certain toxins, by-products, or

chemicals, found unnaturally in the blood stream, and perhaps in the cerebral fluid surrounding the brain and within the ventricles.

Just what degenerative changes may take place in the cells of the cortex due to disease or hypertrophy of the pituitary or pineal gland, I am not prepared to say; but that mental and physical health and normal metabolism are dependent to a great extent upon the harmonious action and interaction of the endocrine glands and gonads, is recognized by all physiologists and pathologists. Then, too, in the processes of digestion and assimilation there are certain other juices and secretions of the stomach, liver, pancreas, intestinal glands, etc., which are poured out temporarily in the blood and lymph streams, and just what effect vitiation, from any cause, of these secretions may have, must be reckoned with also, as well as deficient action of the excretory organs.

The consensus of opinion just now, however, points with steady finger to disease or disharmony of the ductless glands, and to focal infection—whether of teeth, tonsils, nose, ears, or other portion of the body—as the main etiological factors in the production of dementia præcox.

All down through the ages mental disease has been shrouded and obscured by a cloud of mysticism and superstition, which not only hindered, but prohibited its scientific study and investigation, until the physical basis was lost sight of, until now when the pure white light of science is penetrating the mists of this neglected field.

At the present time in treatment, the removal of focal infections, dieting—especially in making use of the vitamins of certain foods, the use of glandular hormones, occupational therapy, amusements, exercise, suggestion, etc., are producing results in a great number of cases which were considered incurable and impossible heretofore. I have had a number of cases under my charge not only of the first, but of the second attack, which made marvelous improvement under the above treatment and regime. But the subject needs much elucidation and investigation, for as yet we are only on the threshold—seeing dimly! But enough has been said and done to point the way. Just what curative effects may result from lumbar and ventricular puncture and the withdrawal of cerebrospinal fluid and from "washing" the blood at intervals with physiological salt solution remain for the future to determine.

123 DIVISION AVENUE.

The "Kif" Smokers of Algeria.—An article on the "gandia" smokers of Mauritius recently appeared in a French medical journal and now we see another with the above title. Both "gandia" and "kif" are local names of Indian hemp. The habit prevails among the lower ranks of indigenous Algerians, and the use of the drug causes a pleasant form of intoxication without excessive motor phenomena. The substance kif is not pure hemp, but mixed with other active substances, including a tobacco known as *souffi*. Kif is cheaper than alcoholic drinks, and so far as known is less dangerous. But kif is not the only resource of the native. His *chira* seems to be pure hemp, and he also uses hashish by the mouth in the long well-known confection (said by many to contain both hemp and opium), while the *naïfoun* which he imports from the Orient is thought to be pure opium.—*Le Progrès Médical*.

MEDICAL RECORD.

New York, April 23, 1921.

THE NARCOTIC BILLS BEFORE GOVERNOR MILLER.

WE would call special attention to a communication in this issue from Judge Cornelius F. Collins, Justice of the Court of Special Sessions and for years Chairman of the Committee on Narcotics of the Magistrates' Association of this State. As penned by a leading authority on narcotic law in this State, and one of the best informed men on the subject generally, his letter is especially valuable at this time and throws important light upon the real drug muddle, which seems to be even more a muddle of administration than one of law. Apparently what we have needed and still need is not so much more laws (save the mark!) or radically different laws as the wise and honest enforcement of the meaning and intent of the laws that we have.

We have apparently not been following the law at all, but have been governed by arbitrary administrative opinions, and have been forced to observe certain rules and regulations which were not contemplated in the law itself and which, as Judge Collins points out, even acted in some instances practically to repeal the law. In other words it seems that we have been governed, or allowed ourselves to be governed, by administrative opinion written into arbitrary rules and regulations, and not at all by real administration of the actual law which was designed to have an entirely different effect.

It is in tardy but growing appreciation of these facts that medical men are endorsing the Second Lord Bill, which retains the essential law as worked out from experience and legislative investigation and study, but which abolishes the Narcotic Commission through which most of these difficulties and uncertainties have arisen, and nullifies the regulations and interpretations exercised by it which have worked out so harmfully.

It is in the hope and expectation of restoring normal interpretation and the exercise of common sense that the Second Lord Bill is supported and urged upon the Governor for his signature. It is also in growing appreciation of the real causes of the present situation, with its recognized increase of criminal underworld smuggling and drug traffic and its driving of honest medical men away from

their duties in the study and care of the deserving and innocent addicted sick, that there is such general opposition to the indefensible Fearon-Smith Bill. Its fallacies and menaces were so clearly shown in open hearing last year, when it appeared as the Cotillo-Smith Bill, that it was actually withdrawn by its introducer, Senator Cotillo. The viciousness of the present bill was demonstrated by a mass of reliable evidence at the hearing on March 6, and one cannot doubt that the Governor, after a study of facts of the situation brought out at this hearing, will refuse to sign any such measure. There are too many authoritative, disinterested, and informed persons—lawyers, physicians, and social workers—unalterably opposed to it in the interests of public welfare, of medical science, and the prevention and suppression of criminal traffic in narcotics to permit of entertaining the thought that Governor Miller could, if at all informed of all the facts, possibly consider the Fearon-Smith Bill.

The only sane and reasonable solution of the problem is to enact the Second Lord Bill, if only as interim legislation, and then immediately to enter upon a thorough investigation and study of the scientific and other needs of the situation. The concluding paragraph of the report of the Public Health Committee of the Academy of Medicine is to the point. In this it was stated that the whole question of drug addiction needed a dispassionate thoroughgoing consideration in its various aspects on the part of the medical profession.

LOCALIZED PLEURAL IRRITATION AND SYNCOPAL ACCIDENTS.

ALTHOUGH some surgeons, seduced by the simplicity of technique and the generally remarkable tolerance of the pleura to operative maneuvers, have perhaps lost sight of the existence of pleural reflexes, others on the contrary have exaggerated the danger. Montaz and Pierry have each recently reported deaths from syncope following an injury to the pleural cavity. Montaz's patient had been hit with a bit of exploding shell and an operation of small importance for its removal, on account of rather alarming symptoms, resulted in the death of the patient a few hours later from syncopal accidents. In Pierry's case death suddenly occurred while the patient was being radiographed for a bullet in the thorax. Pierry says that the reflex caused by splinters of bone irritating the pleura during forced breathing for the radiograph was the cause of death, since autopsy revealed no other cause. The susceptibility of the pleura to certain local irritations, in appearance of minimum importance—exploratory puncture for example—has been recognized for a long time and the accidents to which they may give rise have been minutely described by Bouveret, Cestan, Roch, and others. The clinical modalities have been studied, although they have been subdivided perhaps a little artificially, but an attempt has been made to grasp the etiology and pathogenesis in order to fix upon a rational treatment.

Hypotheses are not wanting for explaining these

reactions, and although some are ingenious their very number sufficiently shows the complexity of the phenomena and the difficulties encountered when their internal mechanism is to be explained. There are the toxic theory, and the theories of sudden depression, embolus, and cerebral anemia, the uremic and the reflex theories, to mention the more important.

In certain remarkable experiments Cordier has shown the capital part played by reflexes in the production of these accidents, whose starting point is the irritation of the pleural terminal filaments of the pneumogastric nerves. It would seem to be a fact that this nerve is alone concerned and not the phrenic, intercostals, or sympathetic, as many have supposed. Syncopal or convulsive phenomena, hemiplegic or parietic accidents, vasomotor disturbances, minor and major nervous accidents, observed both clinically and experimentally in lesions of the pleura are all phenomena of the same order. They are reflexes arising in the rich nerve arborizations described by Rubashkin and Romanoff, in the deep stratum of the visceral pleura, the pneumogastric being the centripetal route. Cordier very rightly insists on the essential part played by localized irritations of this serosa. Every pleural irritation is not the origin of a violent reflex; on the contrary, experience during the war has confirmed what was already known, namely, that the healthy pleura easily supports massive excitation affecting large areas, quite in contrast to the peritoneum.

The study of the blood-pressure during thoracotomies is a demonstration of this. While the pressure curve during laparotomies offers variations from a few centimeters of Hg. to complete syncope, according to the manipulations made on the peritoneum—traction on the intestine, mesentery, etc.—the sphygmomanometer appears to remain quite indifferent to surgical manipulations on the lungs and pleura. It, however, must not be forgotten that this is generally the case and that massive irritation of the pleura is not without its risks, even when the interference does not require the infliction of traumatic insults to the parts. Pleural reflexes explain certain serious accidents, paradoxical in appearance, occurring during thoracotomy or shortly after the thorax has been closed. There therefore exist in the pleura certain particularly sensitive areas whose excitation is susceptible of causing phenomena of shock. Their topography is not as yet clearly defined and all that can be said at present is that they exist.

TESTICULAR GRAFTING.

FALCONE publishes some personal experiments in this province and attempts a chronology of previous efforts in the same direction. Voronoff was by no means the first to perform experiments and operations involving the male gonads but like his remote predecessor, Brown-Séquard, he was the first to obtain popular reclamation (*La Riforma Medica*, Dec. 18, 1920, xxxiv, 51). The Americans were the pioneers in this field and Lespinasse grafted a

testicle (homograft) successfully in 1913 and was followed a year later by Morris, and he in turn by Lydston, who took up the subject in serious fashion and has made a series of important contributions to the subject. Leichtenstern seems to have been the first European to operate, in 1916. Lissmann and Hirschfeld originated the belief that homosexuals might be made normal by testicular grafting and it is said that the experiments along these lines were quite successful, but details fail. A claimant to early honors was Mariotti, although his work, which was done in 1915, could not well have been reported until after the lapse of years. The case was one of testicular grafting in a case of infantilism, which gave the desired result. The author is silent on the recent work of Steinach and Leichtenstern, which is presumably known to the average reader. The details are covered in Steinach's recently issued work entitled "Rejuvenation" which contains an account of the new method of ligating the vas deferens in suitable cases, thus giving all the benefits of homografts. None of the preceding reports refers to heterografting.

Falcone now gives a résumé of four cases of heterografts as follows: (1) Man aged 74, impotent many years; chronic bronchitis and arteriosclerosis. A piece of ram's testicle was embedded subcutaneously under the skin of the abdomen. The wound healed about the tenth day, and already by the seventh day there had been an erection. The wound reopened later and the graft came away with its seminiferous tubules still recognizable; the potency was lost although the patient claimed that his general condition was improved. (2) Man 63, no erections for several years. General condition poor, cachectic, with large varicose ulcer. Heterograft of same type as in Case 1. Erection on seventh day. Graft failed to take and sloughed away, but the erections persisted, for a time at least, while the large ulcer had started to heal. (3) Man of 53, dystrophic and of eunuchoid type with hypoplastic genitals. Malaric and alcoholic. He was married and was originally able to copulate but had been impotent for a year. He presented the appearance of premature senility. Heterograft, ram's testicle. Erection by third day, testicles became swollen and sensitive. Graft came away on eighteenth day but the patient, writing some time afterward, claimed to be potent. (4) Man 69, very robust but complained that he was losing his potency. The same operation was performed, and by the third day there was a violent erection with erotic sensations. During the next sixteen days he copulated several times. The graft healed in, his general condition improved, and the potency was satisfactory.

POISONING BY SODIUM SILICATE.

PROFESSOR EICHHORST, writing in the *Schweizerische medizinische Wochenschrift* for November 25, 1920, i. 48, states that generally speaking silicates are presumably nontoxic and quotes from

standard works on toxicology to this effect. This statement seems to hold good for animals but Schulz once reported that an experimental squad of students developed a chronic poisoning, the symptoms comprising headache, vertigo, somnolence, lassitude, nervousness, tremor, unsteadiness of movements, furunculosis, eczema, hyperidrosis, increase in rate of nail growth, meteorism, borborygmi, diarrhea, colic, tenesmus, notably yellow stools, polyuria, and dysuria, heaviness in the limbs, pains in the bones and joints, stiffness of the joints and painful muscular hypertonus. The author has been unable to find any record of acute poisoning from this substance. But if the matter is scrutinized carefully it is readily seen that opportunities for poisoning have always been absent until quite recently. The silicate of soda has never been used in household economics until of late years as a substance for egg packing and preserving. The author had recently attended a case of acute poisoning from the silicate, probably the first to get into literature. The patient was a robust man of 52 who had poured himself a glass of what he had supposed to be white wine. This he swallowed at a gulp, about six or seven ounces. He felt at once pain in the throat and stomach of a burning character and on examining the bottle found that he had drank a solution of sodium silicate. He developed symptoms suggestive of mild gastroenteritis with much weakness and headache. The tongue, cheeks, and pharynx presented a white coating but there were no signs of caustic action about the lips.

After narrating the case to the period of complete recovery, which comprised four days, the author sums it up as follows: Commercial silicate of soda, known conventionally as soluble glass or waterglass, caused acute poisoning of the irritating type, the mucosae showing also some caustic effects. In addition to the usual gastroenteric symptoms there was evidence of irritation of the kidneys in the shape of albuminuria and casts and blood corpuscles. The blood count showed evidence of stimulation of the lymphnodes and bone marrow. There was a temperature rise while the urine contained small quantities of sugar and acetone. A slight rise of blood pressure may have been due to the renal lesion. The patient had vomited freely soon after swallowing the poison, else he might have been much more seriously affected.

The question at once arose, was it the silica, the alkali, or an impurity which was chiefly responsible for the symptoms? The alkalinity was found to be equal to 9.2 per cent. of soda lye and this might have been sufficient to cause albuminuria, but the urine of the patient had been acid throughout. No impurity is mentioned and in regard to the relative parts played by silica and soda the question is left open.

BLOOD PRESSURE AND MENTAL EFFORT.

THIS subject has recently been investigated by two medical women, Mmes. Toulouse and Tarcowia (*Le*

Progrès Médical, February 5, 1921, xlix, 6). The paper was read before the Clinical Society of Mental Medicine last January. Under mental effort in normal subjects systolic and diastolic pressures rise 3-5 cm. of mercury, and remain thus elevated until cessation of the effort, when the tension rapidly falls to normal. In defectives submitted to effort tests, there was no rise of pressure, results which indicate that no effort worth mentioning was made, and the same negative result was obtained in maniacs and melancholics. Between these extremes there were many transitions. Senile dementers, or those with mental processes presumably weakened, often showed an almost normal maximum, while at the end of the effort the minimal had become depressed although the maximum was still rising. The writers impute this behavior to premature fatigue. In these cases the product of the effort was poor. This reaction of the senile dement or of dementia *per se* is of value in differential diagnosis of mental confusion. In fact lowering of the diastolic tension is the most delicate sign and one of the earliest for mental enfeeblement. It was also learned in the experiments conducted by the writer that there is often a correspondence between mental and physical effort, when the latter is tested with the Henry dynamometer, in both normal and mentally enfeebled subjects. This appears at times as a dissociation of the two curves.

STATUS OF SEROTHERAPY.

RICHEL junior, writing in the *Journal de médecine et de chirurgie pratiques* for January 25, 1921, cviii, 2, gives a summary of the status of serotherapy which, so he says, began in 1888 when his father in conjunction with Héricourt demonstrated that the blood of a dog which had been treated with a special staphylococcus immunized rabbits which were very sensitive to this organism. Whole blood was injected in this demonstration. The results were not published until December, 1890, after the procedure had been tried out on man. The French authors had anticipated Behring and Kitasato by about two years although the two papers were published in the same month. The latter authors secured all of the glory because of the immediate practical nature of their discovery. During the entire period beginning with 1890 the field of serotherapy has been active. In regard to preventive serotherapy we have thus far made good in four affections—tetanus, diphtheria, bubonic plague, and snake-bite. In regard to curative therapy the authors mention seven diseases in which great results have been accomplished, as follows: diphtheria, tetanus (serotherapy is often of benefit in the individual case but cannot dominate the classical disease), bubonic plague (excepting the pneumonic form), Shiga dysentery, cerebrospinal meningitis (recent results have been brilliant), and miscellaneous. Among the unsettled affections in the authors' opinion are gonorrhea, anthrax, streptococcemia, and tuberculosis. Anthrax is doubtless not yet admitted because it has not been shown that serum can cure true anthrax sepsis. In regard to fatal serum sickness twenty cases are on record. Of these but one has occurred in France, a mortality of 1 to about 10,000,000 serum injections.

News of the Week.

Soldiers Not Neglected at Fox Hills Hospital.—

A special committee of Caduceus Post, American Legion, appointed to investigate Fox Hills Hospital, where mistreatment and neglect of soldier patients are alleged to have occurred, reports that the main trouble at the hospital is lack of discipline and co-operation on the part of the patients. The committee found that the hospital staff, except for the laboratories, was entirely adequate, and the dining rooms and kitchens were in first-rate condition of cleanliness. The report recommends that psychiatric cases and the tuberculous be removed to other institutions, and that the drug addicts be more isolated from the rest of the institution. The investigating committee consisted of Dr. Henry C. Coe, Dr. Graeme Hammond, Dr. Harlow Brooks, Dr. Nathan S. Jarvis, and Dr. Samuel Lloyd.

Physicians May Prescribe Wines Without Limitation.—

After having made a tentative set of regulations to control the prescription of wines and beer, which were as drastic as it was possible to make them under the Palmer ruling, enforcement officials in Washington have placed a new interpretation on the prohibition rulings and have decided that it may be safe to permit physicians to use their own judgment in prescribing for patients. Director O'Connor now states that the physician's prescription need not be limited to one pint of whiskey for a patient in ten days, but that vinous liquors may be added "in such quantities as the physician in his sound judgment deems necessary." Director O'Connor warns physicians to use extraordinary care not to abuse this right and advises druggists for their own protection to fill prescriptions for wine only after careful scrutiny to see that excessive amounts are not prescribed.

A Clinical Morning at the U. S. Naval Hospital, Brooklyn.—The commanding officer, Captain C. H. T. Lowndes, Medical Corps, U. S. Navy, has invited the physicians attending the meeting of the State Medical Society to visit this hospital during the morning of May 3 from 9 to 12 o'clock. The hospital and grounds will be open for the medical profession. During the morning clinics will be held in the following departments: Surgical, Physiotherapeutic, Roentgen-ray, Medical, Eye, Ear, Nose, and Throat, Genitourinary, and Neurological. Moving pictures, showing various activities of the Medical Corps of the French Army in the World War, will be on view in the recreation hall continuously between 9 and 12 o'clock.

Summer Courses in Medicine at Columbia University.—A course in cancer research will be given at the Crocker Laboratory, Columbia University, during the coming summer, under the direction of Professor W. H. Woglom of the laboratory staff. The instruction will deal with the morphology and biology of tumors, and will consist of series of lectures and laboratory exercises intended to give sufficient experience to enable the student to diagnose all the commoner varieties of tumors. The course is planned especially to meet the needs of those who are to take up hospital or public health laboratory positions which may require the microscopic diagnosis of tumors. A series of courses in medicine will also be given this summer by the College of Physicians and Surgeons. Professor O. S.

Strong will teach neuroanatomy at the Neurological Laboratory, and a course in clinical pathology will be directed by Professor K. M. Vogel, at the Laboratory of Clinical Pathology. Dr. P. C. Potter will give instruction in minor surgery and bandaging at the Vanderbilt Clinic. Other summer courses will be given in anatomy and bacteriology.

New Rules Regarding Schick Test Outfits and Toxin-Antitoxin.—The New York City Health Department announces that the demand by practicing physicians for material for the Schick test and the Schick-test-control, as well as for toxin-antitoxin has become great enough to warrant the Health Department undertaking their distribution through consignment stations. The number of stations has been limited for the present in order to prevent wastage. For the time being physicians can obtain these products without charge for use on residents of New York City. New Schick-test and Schick-test-control outfits are being prepared, for which a charge of 25 cents each will be made. At the same time toxin-antitoxin will also be supplied, at the price of 25 cents. These new outfits will be ready for distribution about May 1. Free distribution to clinics, hospitals, and custodial institutions will, however, be made as heretofore from the Central Laboratory. The Department of Health is ready to do the Schick test, and inject toxin-antitoxin free of charge. This work is being done at the Baby Health Stations and Department Clinics.

Fire in Camden Hospital.—A fire occurred in the Cooper Hospital, Camden, N. J., on April 9, which caused an estimated loss of about \$50,000. No lives were lost.

The World's Lepers.—The recent announcements in reference to the cure of leprosy with refined chaulmoogra oil have led to the compilation of interesting statistics. It is estimated that there are 3,000,000 lepers in the world to-day. Of these 2,000,000 are in China, 200,000 in India, and 20,000 in Japan. The United States has a big leper problem in her hands in Hawaii and the Philippines.

Bubonic Plague at San Juan.—A despatch received in Washington on April 11, states that a number of cases of bubonic plague have occurred at San Juan, Porto Rico.

Maternity Center Bill.—The Stitt bill passed by the New York State Legislature, would permit various communities to provide funds for maternity care. The Maternity Center Association of New York and others interested in prenatal work are urging support for this measure. They point out that in Manhattan alone last year one mother died for every 205 babies born, and one baby out of every 26 died under one month of age, a total of 2,145. One out of every 20 babies was born dead. In the registration area of the United States 100,000 babies under one month of age die every year and another 100,000 are born dead. Those in favor of the bill point out that the care of mothers and babies is a distinct city or State responsibility.

Druggists Protest Against Prohibition "Black List."—At the tenth annual convention of the American Drug Manufacturers' Association which met in New York April 11-13, a report was presented and resolutions passed urging amendments to the Volstead act. The druggists express a desire for the restoration of the nineteen legitimate pharmaceutical preparations which have been

placed on the prohibition "black list" by the Government. They state that these preparations have been regularly prescribed by physicians for a century and are strictly medicines and not drinks.

Toledo Hospital Loses Radium.—Six thousand dollars worth of radium was accidentally dropped into a catch basin in St. Vincent's Hospital, Toledo, Ohio, on April 14. The sewers of Toledo are being searched by an expert from Pittsburgh in the hope of recovering the radium.

Blackwell's Island Changes Name.—The New York City Board of Aldermen recently adopted a recommendation, submitted by its Thoroughfares Committee, changing the name of Blackwell's Island to Welfare Island. The recommendation will have to be signed by Mayor Hylan before it becomes effective.

Drive to Aid Blind.—A campaign to raise \$2,000,000 for the relief of the blind men, women and children of America, France, and Italy was inaugurated on April 14. President Harding will serve as patron of the Committee for Lighthouses for the Blind. The Post Office Department announces that beginning May 10, there will be a reduction of postage rate on printed matter for the blind to one cent for each ounce or fraction, when addressed for delivery to foreign countries.

Hospital Site Offered.—Mahlon N. Haines has offered a five-acre tract of land near York, Pa., as a site for a new hospital for the construction of which the will of the late Dr. James A. Dale has provided between \$150,000 and \$200,000. No definite action has been taken on the offer.

Fund for Medical College.—The trustees of the Albany Medical College announce that the college has been offered a maintenance fund of \$30,000 annually provided a similar amount is raised each year by the trustees. Of this sum the Rockefeller Foundation will give \$20,000; the General Electric Company \$5,000, and Dr. Charles Alexander Richmond, president of Union University, \$5,000. The money this year must be raised by June 1 to make the \$30,000 available.

Charitable Gifts and Bequests.—The Board of Trustees of the University of Cincinnati, at their meeting on April 5, announced a gift of \$25,000 by Mrs. Minnie F. Ransohoff to the Medical College of the University of Cincinnati toward an endowment fund for the establishment of a chair of surgery to be known as "The Joseph Ransohoff Professorship of Surgery and Anatomy."

The will of Mrs. Elizabeth Southmayd distributes more than \$1,000,000 to charity. Of this sum St. Luke's and the Roosevelt Hospitals, New York, each receive \$100,000; the New York Association for Improving the Condition of the Poor and the New York Association for the Blind, each \$50,000; the State Charities Aid Association, Woman's Hospital, New York Eye and Ear Infirmary, Society for the Relief of the Ruptured and Crippled, New York Orthopedic Dispensary and Hospital, each \$25,000.

Among the many philanthropies receiving bequests under the will of the late Mrs. Mary B. Dortic is the New York Institution for the Blind, which is the recipient of a bequest of \$25,000. Dr. John E. Stillwell has also received a legacy of \$50,000 under the will in appreciation of his services to the testator and her husband.

Gift to Disabled Soldiers.—Mrs. Horatio N. Slater of New York has given her estate at Reads-ville, Mass., to the United States Government for fifty years as a home for permanently disabled soldiers. The house will accommodate 100 men. The home will be called the Morris Hunt Memorial Park in memory of Mrs. Slater's father.

Dr. William S. Thayer has submitted his resignation as Professor of Medicine at Johns Hopkins University. Dr. Rufus Cole of New York and Dr. Palmer of Johns Hopkins are mentioned among the possible successors to Dr. Thayer.

Dr. Amos Baker, formerly psychiatrist of the East View Penitentiary, has been appointed superintendent and psychiatrist to the Bedford Reformatory for women, at Bedford, N. Y.

Dr. Donald Guthrie of Sayre, Pa., has been appointed surgeon in chief of the Lehigh Valley Railroad.

Dr. Thomas J. Cummins has resigned as head of the Arizona State Hospital for the Insane.

Dr. Maria Drew has been appointed school physician of Quincy, Mass.

Dr. E. A. Barber has resigned his position as superintendent of the Ohio State Hospital for the Insane at Dayton.

Prof. Lafayette B. Mendel has been appointed Sterling professor in physiological chemistry at Yale University. This professorship has recently been established by the trustees of the estate of John B. Sterling, who left the residue of his estate in the interest of Yale University.

The Illinois State Medical Society will hold its seventy-first annual meeting in Springfield, on May 17 and 18, 1921.

Medical Society Elections.—THE HORNELL (N. Y.) MEDICAL AND SURGICAL SOCIETY, at its meeting held April 6, 1921, elected the following officers: *President*, Dr. George Taylor; *Vice-President*, Dr. C. R. Bowen; *Secretary and Treasurer*, Dr. George Conderman.

THE NEW LONDON COUNTY (CONN.) MEDICAL ASSOCIATION, at its meeting held at the Norwich State Tuberculosis Sanatorium, April 7, 1921, elected the following officers for the ensuing year: *President*, Dr. C. F. Ferrin, New London; *Vice-President*, Dr. C. C. Gildersleeve, Norwich; *Secretary and Treasurer*, Dr. A. C. Freeman, Norwich.

THE OTOE COUNTY MEDICAL SOCIETY, at its annual meeting held at Nebraska City, March 31, 1921, elected the following officers: *President*, Dr. J. A. Koser; *Vice-President*, Dr. Thomas; *Secretary-Treasurer*, Dr. Wilson.

Red Cross Proposes Limitations in Warfare.—The International Red Cross Conference in Geneva has adopted the following resolutions proposing new limitations in warfare: 1. Absolute prohibition of the use in any way of gas in warfare. 2. Limitation of aerial war to military objects, in order to protect civilians from the effect of this new method of war and avoid useless destruction. 3. Strict application of Article XXVI. of the rules of land war, according to the Hague Conference. Strict application is also recommended of Articles I. and IV. of the convention relating to naval bombardments and prohibiting the bombardment of all undefended places. A proposal has also been made providing for the removal of children, the sick, and the aged

from an area in the case of an economic blockade. This proposal is considered difficult of accomplishment, but it is hoped the different governments will come to an understanding on the question from the humane viewpoint. It is easy to establish limitations but not so easy to insure that the Germans will not again ignore them when they start the next war.

Plans for Child Health Demonstration.—Some weeks ago the National Child Health Council announced that plans were being developed for a child health demonstration with the purpose of aiding in the general movement for the conservation of child life and health. More mature plans are now announced. An appropriation of \$200,000 has been set aside for the purpose of assisting some American community of between 20,000 and 30,000 population and the surrounding country in securing as nearly as possible ideal conditions for the development of its children, from babyhood to adolescence. The requirements of the town to be selected are that it should be located in a county of between 50,000 and 60,000 population. The population should be fairly stable; the age distribution fairly near the average, especially as to the percentage of children and babies; there should be no strikingly predominant racial stocks; the town should have a normal percentage of the population engaged in manufacturing; there should be a variety of industries; the surroundings should be agricultural, and the town should be in a birth registration state. The committee which will recommend the town to be chosen consists of Dr. Richard A. Bolt of Baltimore, Miss Ella Phillips Crandall of New York; Dr. Charles J. Hatfield, Miss Sally Lucas Jean, and Dr. Haven Emerson of New York, and Dr. Donald B. Armstrong of Framingham, Mass. The direction of the experiment will be under Clarence King.

One Board for Care of Disabled Veterans.—In view of existing conditions in regard to the care of disabled soldiers, sailors, and marines, as shown by an investigation carried out by a committee especially appointed for this purpose, of which Charles W. Dawes is chairman, recommendations have been made to President Harding that he ask Congress for the necessary legislation to create "The Veterans Service Administration," and in this governmental bureau to place the new Bureau of War Risk Insurance, the Rehabilitation Division of the Federal Board for Vocational Education, and such part of the Public Health Service as has to do with the care of disabled veterans. At the head of this new bureau the committee wants a director-general, who shall be directly responsible to the President, and not some cabinet officer already burdened with other duties. Seven specific recommendations are made by the committee for bettering the care of ex-service men. One of these is the immediate extension of all government hospital facilities, together with the mobilization of such civilian medical services as may prove practical.

Doctors Oppose Occupation Tax.—Representatives of the medical profession of Louisiana appeared before the Tax Committee, at its adjourned session on March 29, to protest against being placed in a class with trades and made to pay a license tax for the practice of a professional calling. Dr. Ho-

mer Dupuy, President of the Louisiana State Medical Society, gave as reasons why this tax should not be imposed on physicians that Louisiana was the only State that imposed such a levy; that doctors gave to the State annually \$2,000,000 worth of systematic charity, and that physicians should not be classed as tradesmen but as members of a dignified profession.

Damages for Appendicitis Death.—A jury in the Supreme Court of Brooklyn, N. Y., recently returned a verdict of \$6,500 against the New York Consolidated Railroad Company in favor of the estate of the late Herbert W. Goward, injured in the Malbone Street tunnel wreck in November, 1918. Goward died of appendicitis nine months later. The counsel for the Goward estate produced medical proof showing that appendicitis was a germ disease; that germs existed in the bodies of all ordinarily healthy persons; that the illness Goward had suffered as a result of his injuries had caused a clogging of the intestinal tract; that the circulation of the blood through the appendix was retarded, and that thus a breeding place for germs was created.

Medical History Collection in the Lane Library.—With the aid of a gift from Dr. Adolph Barkan, emeritus professor of the Stanford Medical School, the University is gathering in the Lane Library of the Medical School in San Francisco a collection on the history of medicine that will be equaled by no other western institution. Dr. Barkan will give \$1,000 a year for the next three years, to which the University will be able to add from the income from certain Lane Library Foundations \$1,500 a year, making a total fund of \$7,500, all of which will be expended on books concerning the history of medicine. Dr. Barkan was professor of structure and diseases of the eye, ear, and larynx in the Medical School and retired from active teaching in 1911. He has before this been a liberal benefactor of the Medical School Library, having given his own library dealing with the subjects in his special field, together with \$10,000 as a fund for the purchase of other books on these subjects.

City Votes for Hospital.—A vote as to the advisability of levying a special tax to provide funds for the purchase of the Cedar Valley Hospital for Charles City, Ia., resulted in a majority vote in favor of the purchase.

Buffalo to Have Government Hospital.—A new Government Hospital to cost \$100,000 to \$150,000 is to be built at Fort Porter to care for disabled veterans of the world war.

New State Hospital for West Virginia.—A farm of six hundred and fifty acres has been purchased in Mason County, W. Va., as a site for a proposed State Hospital for Insane Negroes.

Campaign for Bristol Hospital.—Final plans have been completed for launching a campaign to raise \$150,000 to be used in erecting a hospital in Bristol, Tenn.

The Pope County (Ark.) Medical Society. at its meeting in Russellville, March 26, elected the following officers for the ensuing year: *President*, Dr. R. L. Smith; *Secretary*, Dr. H. S. Drummond.

Alcoholic Patients Fewer.—The records of the Middletown State Hospital, Middletown, N. Y., show a marked decrease in the percentage of alcoholic patients. Several years ago about 8 per cent.

of the patients in this institution were alcoholic; at present not even one per cent. can be placed in that classification. According to the records of this institution the number of drug cases is not increasing.

Obituary Notes.—Dr. LEO JOSEPH COMMISKEY of Brooklyn, N. Y., died following an operation for appendicitis on April 15, at the age of forty-two years. He was graduated from the College of Physicians and Surgeons, New York, in 1904, was a Fellow of the American College of Surgeons, and a member of the American Medical Association. He was gynecologist and obstetrician to the Kings County and Bradford Street Hospitals, Brooklyn, and consulting obstetrician and gynecologist to the Mercy Hospital, Hempstead, L. I. During the war Dr. Commiskey was a Major in the Medical Corps of the Army.

Dr. SAMUEL ALEXANDER STERRETT METHANY of Philadelphia, Pa., died at his home in Philadelphia, on March 26, at the age of fifty-one years. He was graduated from Jefferson Medical College, in 1894, and served as captain in the M. C., U. S. A., having been discharged in June, 1919. He was a medical missionary in Syria for some years and a member of the Royal Microscopical Society of London.

Dr. RANSFORD EVERETT VAN GIESON, for over fifty years a practising physician of Brooklyn, N. Y., died of pneumonia, on April 1, at the age of eighty-four years. He was a graduate of the College of Physicians and Surgeons, New York, in 1859.

Dr. FREDERICK SAUER of Hammond, Ind., a graduate of the University of Michigan, in 1902, died in a local hospital of pneumonia, on March 23, at the age of forty-three years.

Dr. SAMUEL PRITCHARD FETTER, a graduate of the Miami Medical College, Cincinnati, in 1904, died suddenly of Bright's disease at his home in Ashland, Ky., on March 18, at the age of thirty-nine years.

Dr. ARTHUR J. GILLETTE of St. Paul, Minn., died suddenly of cerebral hemorrhage, on March 24, at the age of fifty-eight years. He was graduated from the St. Paul Medical College in 1886. He was for many years professor of orthopedic surgery at the University of Minnesota, and was founder of the Phalen Park Hospital for Crippled Children, St. Paul.

Dr. C. W. COBURN of Philadelphia died on a train at Carrizozo, N. M., while en route to California for his health, on March 29, at the age of fifty-four years. He was graduated from Jefferson Medical College, in 1893, and was for many years chief of the nose and throat clinic of Jefferson Hospital.

Dr. CORNELIUS L. DEMOREST of Washington, D. C., a graduate of Bellevue Hospital Medical College, in 1879, died on April 2.

Dr. ERNEST SCHALCK of Brooklyn, N. Y., a graduate of the University of Wurzburg, Germany, in 1882, died on April 15, at the age of sixty-two years. He was chief ophthalmologist to the Wyck-off Heights Hospital, consulting ophthalmologist to the Beth Deaconess Home, and assistant surgeon to the Knapp Memorial Hospital.

Dr. CHARLES HAINES of New York, a graduate of the Long Island College Hospital in 1908, died suddenly on April 12, at the age of forty-five years.

Dr. JOSEPH FEWSMITH, a graduate of the College of Physicians and Surgeons, New York, in 1874, died in Newark, on April 9 at the age of seventy years.

Dr. FRANK PEASE HOWSER of Otisville, a graduate of Bellevue Hospital Medical College in 1891, died after a brief illness on March 29 at the age of fifty-nine years. He was a member of National Society for the Prevention of Tuberculosis.

Dr. WILLIAM OWEN ROBERTS of Louisville, Ky., died of chronic nephritis on April 1 at the age of seventy-two years. He was graduated from the University of Louisville Medical Department in 1870, and from Bellevue Hospital Medical College in 1871. He was professor of surgery and clinical surgery in the University of Louisville since 1876, chief surgeon of the Louisville and Nashville Railroad Company for almost forty years, president of the Kentucky State Medical Association in 1914, and formerly a secretary of the American Medical Association.

Dr. O. P. MCNAIR, a graduate of Rush Medical College, Chicago, in 1892, died at his home in Oklahoma City, Okla., on April 2, at the age of fifty-five years.

Dr. DORA GREENE WILSON of Kansas City, Mo., died of heart disease on April 3, at the age of fifty-seven years. She was a graduate of the Northwestern University Women's Medical College in 1886.

Dr. WILLIAM P. BERRY, formerly of Memphis, died in South Pascagoula, Miss., on March 23 at the age of seventy-nine years.

Dr. FREDERICK W. SAUER of Indiana Harbor, Ind., a graduate of the Medical Department of the University of Michigan in 1902, died in a local hospital on March 23, at the age of forty-two years.

Dr. DAVID FRANKLIN of Louisville, Ky., a graduate of the Hospital College of Medicine of the Central University of Kentucky in 1880, died on April 7, at the age of seventy-nine years.

Dr. WILLIAM D. LITTLE of Maiden Rock, Wis., died of heart disease in a hospital in St. Paul, on about March 30, at the age of fifty-three years. He was a graduate of Tulane University Medical Department, New Orleans, in 1887.

Dr. ELMER H. MAURER of Ashland, Pa., a graduate of Hahnemann Medical College and Hospital, Phila., in 1902, died in Tampa, Fla., on March 29.

Dr. HEMAN HAMPTON BROWN, president of the Illinois Medical College, Chicago, Ill., died in Orlando, Fla., on April 10, at the age of fifty-eight years. He was graduated from the Medical Department of University of Michigan in 1886. He was president of the Chicago Ophthalmological Society, and professor of ophthalmology in the Chicago Policlinic and the Chicago Eye, Ear, Nose and Throat College.

Dr. DAVID ROSSMAN of Wilmington, Del., a graduate of the Medico-Chirurgical College, Philadelphia, in 1914, died of heart disease on April 11, at the age of thirty-three years. He was connected with the Delaware Hospital and the Physicians and Surgeons Hospital.

Dr. MILES MINOR GLASS, a graduate of Rush Medical College in 1886, died of heart disease in East St. Louis, Ill., on April 1.

Dr. JEROME M. DAVIS of North, S. C., was instantly killed on April 2, when his automobile was

struck by a passenger train at a short distance from his home. He was a graduate of the medical College of Georgia in 1889, and was fifty-nine years of age.

Dr. GEORGE R. HILL of Kendall, Wis., a graduate of Bennett Medical College, Chicago, in 1886, died on March 24, at the age of sixty-nine years.

Dr. FREDERICK C. SEIBERLING of Allentown, Pa., died on April 4 at the age of eighty-one years. He was a graduate of New York University Medical College in 1862.

Dr. LARNED V. ALLEN of Davenport, Ia., died of scarlet fever on March 31, at the age of thirty-three years. He was graduated from Rush Medical College in 1913, was commissioned Captain in the Medical Corps of the United States Army in 1918, and served as battalion surgeon to the 26th Infantry during the Meuse-Argonne campaign.

Dr. CHARLES B. G. DE NANCREDE of Ann Arbor, Mich., died at his home there on April 13, at the age of seventy-three years. He was professor of surgery and clinical surgery in the University of Michigan. He served as Major in the Spanish-American War, and was president of the American Surgical Association in 1908-09. He was graduated from the Medical Department of the University of Pennsylvania in 1869, and also from the Dartmouth Medical School.

Dr. CHARLES F. ELLIOTT of Bradford, Pa., a graduate of the Medical Department of the University of Buffalo, formerly attached to the staff of the Erie County Hospital and later to the State Hospital for the Insane at North Warren, Pa., died in a local hospital on April 5, at the age of forty-two years.

Correspondence.

THE DRUG LAW MUDDLE.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—My attention has been called to your editorial, "The Drug Law Muddle," in your issue of April 16. If the term Drug Law Muddle was apt at the time your editorial went to press it would be infinitely more apt now for the reason that we have three distinctly conflicting bills presented to the Governor by the Legislature for his deliberation. The muddle, therefore, is one not alone to tax the minds of those interested in the solution of the drug problem from the sociological and medical standpoints, but calls for action so that the entire situation may be placed before the Governor and the right thing done by him in the signing of any of the three bills.

I am prompted to write you so as to set myself straight, or rather you straight on the subject treated in your editorial. First, you suggest that the Magistrates' Association was in part responsible for the present "unsatisfactory law." There have been no indications that the existing law has been in itself unsatisfactory. The "muddle" that you speak of is not due to failure of the statute but to the enforcement of promulgated rules and regulations which were in some instances in their effect tantamount to repeal of the law and contrary to its intents and purposes.

The complaints and protests as I have heard them on the part of the medical profession have been to

the rules and regulations and administrative restrictions made by Federal and State officers in their enforcement of the laws, which had the effect of frightening and discouraging the legitimate practice of medicine in these cases and of reviving peddling and its associated criminal cases coming into court. This I pointed out in my report.

It is to be appreciated that the Harrison Law is a Federal tax law, although aiming to control traffic in drugs. The Supreme Court has decided that police power cannot be exercised under this statute for the reason that the Federal Government is without such power. This is the reason why mere possession without the showing of some definite other violation in the obtaining of the drug was held not to be a crime.

If there were no State law, peddlers and possessors in the underworld would be practically free from molestation in so far as possession is concerned. You can visualize the evils that would result and appreciate that such a condition would arise as would give rise to far more drastic legislation in the future if our whole State law were repealed. In fact the situation might immediately result in a sanitary code form of enactment and lead to a state of affairs that the word "muddle" would be no name for.

It would undoubtedly happen in some large centers that the sanitary code would provide just exactly what the Fearon-Smith Bill provides, which you in your editorial term "monstrous," and would utterly forbid a medical practitioner in private practice prescribing a drug for drug addicts, or make such prescribing practically impossible. This would undoubtedly lead to chaos. I call your attention to the arguments used by me in my report on this matter.

I am impelled, therefore, to push the thought that you expressed that it might be well to adopt the bill recommended in my report, namely, the second Smith-Lord Bill. It abolishes the Commission and leaves the law for the State of New York without the power to permit any further obnoxious administrative restrictions or regulations by administrative officers, but otherwise retains a substantial State law which is the least burdensome to the medical and pharmaceutical professions of any State law in the Union, while at the same time it answers all sociological purposes.

In passing let me suggest to you that the regulations promulgated and imposed were no part of the statute or substantive law. I believe that if practitioners of medicine or pharmacy or their organizations had availed themselves of their legal rights under the law, many of the most obnoxious regulations and rulings would have been upset.

The great importance of this whole situation at this time cannot be too strongly called to the attention of the medical profession, the drug trade, and the sociologists. This is my excuse for the lengthy communication to you, in the realization that you will appreciate its importance and will act in your earliest issue so as to properly line up the forces before the Governor.

CORNELIUS F. COLLINS,

Chairman, Committee on Narcotic Drug Control,
State Association of Magistrates.

NEW YORK, April 17, 1921

FALLACIOUS REASONING IN SUPPORT OF COMPULSORY HEALTH INSURANCE.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—I have rarely read an article conveying more misinformation on a subject than the recent contribution on "National Waste Through Ill Health," by Henry W. Lanier, in *The American Review of Reviews* for March, 1921. In the deliberate campaign of public confusion which is being carried on by laymen making propaganda on health questions this article may be considered typical of what is to-day a serious menace to public interests. Ostensibly a plea for better health, the article merely adds to the existing amount of misunderstanding and leaves no impression on the mind other than that this country has been grossly derelict in health matters and far behind European countries in sanitary reforms. The argument is introduced with the statement that "Our largest remediable waste is that of preventable ill health." In very truth our largest remediable waste is good white paper misused for purposes of public misinformation. An attempt is made to support the argument by a mass of irrelevant conjectures derived from reports long out of date, and there is displayed throughout a colossal ignorance of current facts and figures accessible to anyone who desires the truth. It is absurd as well as pernicious to argue that "We are permitting nearly a million Americans to die each year prematurely." No power on earth can prevent the overwhelming amount of premature sickness or death which has its origin in habits, inheritance, and conditions largely outside of human control. It is equally pernicious and absurd, therefore, to argue that "We have perhaps two million people needlessly sick all the time." No wealth or ingenuity could prevent most of the sickness which prevails and which will continue to prevail to the end of time. But this country is to-day the healthiest as it is physically the most advanced of any country in the world. It boasts to-day of the lowest death rate on record (12.9 per 1,000 of population for 1919), which a few years ago would have been considered absolutely unattainable.

The article continues, "It is a humiliating fact that twenty-three out of our forty-eight States do not furnish us with a registration of deaths." The number of States in the registration area in 1919 was thirty-three, and the total population within the area was 81.1 per cent. The States which are not within the registration area are of the least relative importance, but the area is continually being enlarged as the result of the indefatigable efforts of the Census Office. For the area under observation the returns are as trustworthy as for any corresponding section of the world, and it is therefore a grotesque perversion of the facts to quote antiquated statements in an article published in the year 1921, when a correct statement for 1919 was certainly available and a close estimate for 1920 could have been had on inquiry at the Washington office. For all practical purposes, therefore, we know that the true death rate of the United States for the area not under registration, if known, would not materially alter present conclusions.

The writer makes the statement that the regis-

tration includes about two-thirds of the total population, instead of four-fifths. He further implies that the returned death rate of 14.2 per 1,000 in 1917 was untrustworthy, for he remarks, "Experts believe 18 to the thousand is correct for the whole country." Experts believe nothing of the kind, but the writer no doubt refers to statements made many years ago, when 18 per 1,000 was considered a normal attainable death rate. All investigations which have been made in this country substantially confirm the conclusion that the registration is practically complete and that the resulting death rates are entirely trustworthy. For 1920 the death rate of England and Wales was returned as 12.4 per 1,000. No one questions the accuracy of this return, and there are no reasons for questioning the substantial accuracy of our own returns. There is to-day not a single State in the registration area of the United States with a death rate exceeding 16.0 per 1,000. The conclusions advanced, therefore, as regards the probable number of deaths are as grotesquely erroneous as the corresponding conjectures regarding the amount of preventable illness. There are no statistics of any kind which justify definite assertions as regards the probable prevailing amount of sickness otherwise than as tentative indications of the possible extent of the sickness problem made with a due regard to the point of view from which the question is considered. The writer handles his millions as carelessly as he does his billions. The so-called economic loss from sickness is a mere speculative guess of no intrinsic value whatever.

The writer brings forward the same silly argument that, "Of course, we are far indeed from handling the problem as earnestly and efficiently as we do in the case of valuable cattle or machines." This is always the form of argument used by those who would destroy confidence in the existing order by stating a proposition in a way most confusing to those who are not familiar with the facts. We spend as much upon health and sanitation as any country in the world, when all the facts are taken into account. As the result, we have on the whole as healthy and vigorous a class of people as any nation can point to with pride. We owe this to a public health service—federal, state and municipal—which, on the whole, compares favorably with what is available in other countries. The ignorance of the writer is perhaps displayed nowhere better than in his reference to the "Public Health and Marine Hospital Service," the title of which was changed by Congress to the United States Public Health Service as far back as 1902!

It was to be expected that the writer would bring forward the draft figures as an indictment of the physique of our young manhood. Anyone familiar with draft examinations and the underlying reasons for military selection knows full well that the conclusions are to be accepted with extreme reserve if used for any practical purpose whatever. They do not apply to the population at large, and they do not apply to the problems of preventive medicine, but they apply rather to the system of military recruiting, most urgently in need of radical reforms. Men were rejected for many causes which never hindered them in the pursuit of gaining a livelihood or resulted in any serious illness. Men were

rejected who were fully suitable for military service, because of deficiency in height or deficiency in chest expansion, or flat-foot, etc., although fit for all the ordinary occupations, including many branches of the military service.

Reference is made to an alleged census of 1910 showing some arresting facts regarding the comparative mortality among native-born Americans of native parentage, and the foreign-born or foreign or mixed parentage. The census did not make a proper inquiry into the subject corresponding to a similar investigation made in 1890, and there is not extant at the present time the result of a really trustworthy investigation which would admit of final conclusions as regards the relative mortality of the native-born of native stock, and those foreign-born of foreign stock. It is therefore grossly misleading to argue that "This means that we are weakening our national vitality by admitting physically inferior immigrants," for, broadly speaking, no one is in a position to pass upon this question with finality at the present time. When the Immigration Commission, some years ago, examined into the facts it was found impossible to provide a statistical basis that could be accepted as conclusive. Such data should be based upon the nativity of the mother, for if merely made to consider the country of birth large numbers of the native-born of foreign stock are included with the native-born of native stock.

There was published, however, in 1916, a life-table for the year 1910, according to which the complete expectation of life at age 40 was 28.33 years for native-born white males, while it was 26.03 years for foreign-born white males. For native-born white females the expectation at age 40 was 30.33 years, while for foreign-born white females it was 27.55 years. These results, however, represent mere figures of a vast heterogeneous mass of foreign-born population which may or may not be comparable, according to the point of view. In any event, the differences as indicated are not sufficient to justify the far-reaching conclusion advanced.

The writer argues that, "It ought to be considered a disgrace, to be wiped out speedily, that Pittsburgh has a death rate 75 per cent. higher than Detroit, the whole United States a third higher than Denmark." It is not indicated for what period of time the comparison is made, but for 1919 the death rate from all causes for Pittsburgh was 16.1 per 1,000, against 11.7 per 1,000 for Detroit; and for typhoid fever, which formerly was a local scourge in Pittsburgh, the rate for 1919 was 6.5 per 100,000 against 5.2 for Detroit. There are no statistics by causes for the whole of Denmark, which has registration in detail only for its larger cities. For the whole of Denmark, in 1910 the death rate from all causes was 12.9 per 1,000, against 15.0 for the registration area of the United States. The reference to the whole United States by the writer is so much more amusing, since he had previously indicated that the records were available for only about two-thirds of the population. Hence his conclusion that "There could hardly be a more basic test of community civilization than this very one: *how many citizens die needlessly each year?*" The figures quoted were no test at all; are inapplicable to pres-

ent conditions, and would not under any circumstances warrant a conclusion as to indifference to human life in this country.

The Y. M. C. A. is referred to as having probably "done more for health than any other agency." Granting that it has done much, it is certainly not entitled to the credit for the enormous amount of community service to which we primarily owe the control of numerous infectious and contagious diseases, all of which have been very materially reduced in relative frequency during the last twenty years and without any cooperation on the part of the Y. M. C. A.

The plea is made for a national department of health. The writer advances merely the shibboleths brought forward years ago by the Committee of One Hundred, which failed conspicuously in securing the required action on the part of Congress. There is not a word about recent developments in the Health Center movement, or in the coordination of health-conserving agencies, or of the more deliberate efforts for a reorganized Federal Health Administration based upon totally new conceptions such as have been advanced by Sir James Mackenzie in "The Future of Medicine." The advice that is required is not that of college professors, or of writers, or of propagandists, but of leaders of the medical profession and the public health service throughout the country, familiar with the facts and the needs of the situation. There is the usual lip service of research, but not the slightest indication of any knowledge of what research work is being done, nor is there mention of the International Health Board, the Carnegie Institution, the Rockefeller Foundation, and the long list of voluntary health-promoting agencies, including cancer research laboratories, etc.

It is untrue in this connection to say that "Washington now has the fourth *highest* death rate of our twenty-three largest cities," for, construing "now" to have reference to the year 1919, for which information was available, the death rate of Washington, D. C., for that year was 14.7 per 1,000, which compares with 13.3 per 1,000 for New York City, 12.5 per 1,000 for Chicago, 14.3 per 1,000 for Philadelphia, 13.3 per 1,000 for St. Louis and 15.7 per 1,000 for Boston.

There is the usual plea for complete vital statistics, made by one obviously grossly ignorant of what statistics exist and for what purpose they can be most usefully employed. The writer refers to the chief of the Division of Vital Statistics of the Bureau of the Census as Dr. Cressy L. Wilbur, who resigned to accept a similar position with the New York State Department of Health as far back as 1913. The present chief of the Division of Vital Statistics of the Census Bureau is Dr. William H. Davis, under whose efficient administration the registration area has been very largely extended, with a corresponding improvement in the accuracy of the returns. To quote remarks made by Dr. Wilbur possibly ten or fifteen years ago is but a further illustration of the deliberate purpose to confuse the public.

Every argument advanced by propagandists who are using public health needs for the nefarious purpose of advancing personal interest is utilized Typhoid fever does not, as stated, kill 20,000 persons

per annum in this country, but, conservatively estimated, the mortality from this disease for 1919, for the entire continental United States, was about 10,000. As to what is the "average incapacity resulting from typhoid fever," no one is in a position to state with precision, but in all probability it is materially less than the seventy-five days indicated.

The argument (if such it can be called) concludes with a plea for health insurance such as that recommended by a special committee of the New York Federation of Labor. The arguments advanced in that report were largely fallacious and they were disregarded by the Legislature, which failed to pass the Davenport bill. The assertion that health insurance will provide a powerful stimulant to "the needed campaign for the prevention of illness" is another shibboleth common to those who have persistently disregarded the obvious truth that neither in Germany nor in England has health insurance advanced the cause of community or private health.

The statement concludes with an assertion made by the physical director of a Y. M. C. A. that "the World War saved more hours of life than it destroyed." The war did nothing of the kind. The enormous losses due to the war will never be made good throughout all history. The medical and surgical lessons of the war are a small compensation for that lamentable conflict. But in this, as in other matters quoted, the writer makes use only of an appeal to unreason and to the growing confusion of the public mind, which looks hopelessly into the future when leading periodicals lend their pages to utterances which would disgrace a waste basket.

FREDERICK L. HOFFMAN.

NEWARK, N. J.

OUR LONDON LETTER.

(From Our Own Correspondent.)

LONDON, March 29, 1921.

Influenza Outbreak.—A recent return of the Registrar-General for the United Kingdom shows that in the week ended March 5 last, there were 167 deaths from influenza in London and the other ninety-five great towns of the United Kingdom. The outbreak became noticeable as far back as the week ended December 11, 1920, when 61 deaths were registered. On December 18 and 25 the figures were 75 and 81 respectively. Since the new year the returns have been: January 1, 89 deaths; January 8, 101; January 15, 87; January 22, 66; January 29, 61; February 5, 61; February 12, 91; February 19, 103; February 26, 138; and March 5, 167. There is official warrant for the statement that influenza generally shows a tendency to rise in the month of March. In 1920 the highest point was reached in the week ended March 20, when 392 deaths occurred. In the corresponding week of 1919 no fewer than 3,889 deaths happened. In 1918 a positive epidemic devastated the country, and in the week ended November 9, the Registrar-General made the alarming announcement that 7,557 deaths had been registered. The Registrar-General has announced that the notification of cases of encephalitis lethargica is decidedly on the decline.

Financial Position of Hospitals.—In the House of Commons on March 17 last, in answer to a

question as to when the report of the Committee on Hospital Finances would be published, said that an interim report had just been issued on the question of contributions to hospitals out of the valuation surpluses of Approved Societies. He was informed that the hearing of the evidence would be completed by the beginning of May next and that the committee hoped to present their final report before the end of that month.

Alcoholic Liquors as Medicine.—The Prime Minister was asked in the House of Commons recently whether, in view of the fact that beer as well as whiskey had been recognized as a medicine in prohibitionist America, he would arrange to relax the restrictions imposed upon the people of the United Kingdom under the Defense of the Realm Act and Central Control Board. Mr. Lloyd George replied that the government proposed to deal with this subject at an early opportunity.

Washington Maternity Convention.—On March 22, in the House of Commons, Mr. Clynes, a prominent labor member, and other members raised the question of that article of the Washington Convention which dealt with maternity benefits and asked the reason why the Government had decided not to ratify the article and had not brought it before Parliament in the form of legislation.

Dr. Addison, the Minister of Health, said that the initiation of legislation in this country rested with Parliament, and had the Government ratified the Washington Convention with regard to maternity the position would have been that an outside body would be able to compel the Government to submit legislative proposals to that House against its desires. To that the House would never submit. They had already in this country a system which was double-barreled for providing maternity benefits, namely, the Insurance Act and the system administered by the local authorities. These recommendations cut right across the system in Great Britain which was acting with singular success. The Washington Convention related only to employed, which would mean that in Great Britain about 460,000 women would be eligible, while 3,540,000 women, the wives of insured persons, would be excluded. To carry out these recommendations with regard to all these women would cost an additional £15,000,000 (\$75,000,000). The system of maternity and child welfare cost one penny (two cents) in the pound (\$5) on the rates, rather less than £900,000 (\$4,500,000) being contributed out of the Exchequer. The results had been brilliant. The rate of infantile mortality had dropped from 106 per 1,000 in 1913 to 75 per 1,000 in 1920. There had, of course, been contributory causes. People had been better nourished and the national conscience had been more fully awakened since the war.

Eradication of Tuberculosis in Man and Animals.—On March 14 last a general meeting of the Fellows of the Royal Society of Medicine met to discuss the eradication of tuberculosis in man and animals, the discussion being opened by Sir John McFadyean, principal of the Royal Veterinary College. Perhaps the most generally interesting speech made was by that grand old man of

medicine, Sir Clifford Allbutt, Regius Professor of Physics at the University of Cambridge, who said in part that of the devastation caused by this virulent pest he need not speak, but as Robert Burns thought there might be something to be said even for "Auld Nickie-ben," so perchance to the evil spirit of tubercle some beneficent by-product might be credited. He remembered in the early days of his practice in the north of England how in the valleys of the Dales enteric fever was rampant and endemic; the farmsteads were foul with stench, vermin and disease, but the farmers said that a good manure heap did no one any harm. However, the discovery of the exact causes of typhoidal affections led to a conversion of people who before had turned a deaf ear to all arguments.

The case was the same with tubercle; you might as well have argued with one of his bullocks as with the farmer on the intimate causes of the disease, until the discovery of the tubercle bacillus aroused the public to a sense of the intimate and subtle virulence of germs of disease which could be neither seen nor handled. Tuberculosis, then, was our schoolmaster, to drive into us these truths; a schoolmaster which chastised us with scorpions indeed, but began its serious lessons with those innocents, the butcher and the milkman. No less had been the revelations on glands and the marvelous results in the war of mallein vaccines, results which were almost incredible when compared with the ravages of the disease in former campaigns. Here the education began with the stable boys. Thus the lesson of many such diseases had at last persuaded the man in the street to listen to the truths and prophecies of science.

Obituary.—To the melancholy long list of distinguished medical men who have been martyrs to science must now be added the name of Dr. William Ironside Bruce, radiologist to Charing Cross Hospital, who died on March 21 at the premature age of 44. Many of the early workers with x-rays suffered from dermatitis and some succumbed to cancer and other long and painful illnesses. Protective measures were devised, but the death of Dr. Bruce shows that they are inadequate when used with the newer tubes. The effect, too, is different; the gamma rays which these tubes send forth having a potentially harmful effect on the blood corpuscles and setting up an aplastic condition such as that which proved fatal to Dr. Bruce. He had been ailing for some time, but it was not until January, 1920, that he became seriously ill. It was only a few weeks ago that the true nature of his disease was recognized, but all efforts, including transfusion of blood, were of no avail. The deceased was of Scotch birth and served as a civil surgeon during the South African war. When he returned he set up in practice in London and began his x-ray work at Charing Cross Hospital. He was a remarkably skillful worker, rapid in diagnosis, and much beloved by patients and colleagues. He had already achieved some important results by means of his researches. His untoward and untimely death is a loss to medical science as well as to the cause of the amelioration of human suffering.

2. The Value of the Quasi-Continuous Temperature Record in the Early Diagnosis of Tuberculosis.—Sir German Woodhead and P. C. Varrier-Jones maintain that the quasi-continuous temperature record of a reaction is a valuable diagnostic indication as to (1) the tuberculous nature of the disease; (2) the activity of the process; (3) the prognosis. As to the type of the disease, however, "acute miliary," "caseous pneumonic," "chronic fibroid," etc., though the temperature may give some indication, the physician will find that physical signs afford considerably more specific information. The temperature indications as to the resistance or lack of resistance of the tissues of the patient are of extreme interest, especially in regard to prognosis. Instability of the temperature affords evidence of (a) a high toxic absorption; (b) ready reaction of the tissues to the toxic stimulation; and (c) marked interference with the rest function of the patient. A restless night is reflected in the temperature curve, and it appears that the inverse temperature is, to a large extent, the result of a continued auto-inoculation, during which a minimum stimulus produces a maximum reaction both as to amount and duration. In the night sweats one has evidence of some interference with the autonomic nerve centers, leading to dilatation of the surface blood vessels, great radiation of heat from the cutaneous surface, and a rapid lowering of the general temperature. At the outset of their observations the writers thought it well to compare the rectal temperatures with a series of temperatures taken in the mouth with the ordinary mercury clinical thermometer, but these temperatures bear little relation to the rectal temperatures. In the advanced stages of the disease some information could certainly be obtained from these readings, but they give little indication of the extent or progress of the disease or, in its earlier stages, of its presence.

4. The Chemical Estimation of Gastric Function by the Test Meals of Ewald and Boas.—J. H. Reyfel holds that the fractional test meal gives results that are of great interest, but it serves rather for arranging the cases in various groups than for individual diagnoses. The actual diagnosis must be completed from further considerations, and especially by a clinical study of the individual case.

1. Some Recent Advances in the Physiology of Respiration, Renal Secretion, and Circulation.—J. S. Haldane summarizes the results of a number of recent investigations, with most of which he has been closely associated, on respiration, renal excretion, and circulation, and points out their significance in helping one to understand the symptoms of disease and the real characters of that marvelous living body with which the medical profession has to deal. He discusses the regulation of carbon dioxide pressure in arterial blood; the regulation of the reaction of arterial blood; the regulation of oxygen pressure in arterial blood; renal excretion; the regulation of diffusion of water in the blood; the regulation of diffusion pressure of solids in the blood; and the circulatory regulation of blood composition.

In discussing the significance of physiological regulation he points out that physiological regulation is not only something very real, but it is also extremely delicate. It is only by exact quantitative observations that one can estimate the delicacy of regulation; but symptoms, if rightly interpreted, give an extremely sharp index of failure in normal regulation. Close observation and right interpretation of symptoms is of paramount importance. Regulation to a normal during health implies that the living body actively maintains a normal of structure and activity in spite of ever-changing conditions of environment. From side to side of this normal the living body is constantly oscillating as the result of disturbances in the environment, and constantly tending to return as near as may be to the normal in spite of the disturbance. One can distinguish ordinary physiological disturbances, which the body can easily overcome, from the more serious disturbances which require medical or surgical treatment to assist the return to normal or something approaching it; but apart from the fundamental assumption that it is, to use the old expression of Hippocrates, the "nature" of a living organism to maintain a normal, and to return toward it in spite of disturbance, physiology and medicine seem to be a mere chaos of unconnected empirical observations. It is the reality of organic regulation, and the necessity for the guiding conception of organic regulation, that stand out in the results of the investigations summarized. The aim of physiology, and of every branch of biology, is to render clear by experiment and observation what the normal activities and structure of a living organism are, what the deviations from them really consist in, and how the normal tends to be maintained or reestablished in face of disturbance.

1. The Importance of Recognizing and Treating Neurosyphilis in the Early Period of the Infection.—John A. Fordyce, from clinical and serological work during the past ten years, formulates the following propositions: 1. Syphilis of the nervous system probably begins in the first year of the infection. The number of cases corresponds roughly with the total number of cases of so-called late neurosyphilis. The foregoing statements are based on the following observations and established facts: (a) The number of early cases showing positive findings in the spinal fluid; (b) familial types of neurosyphilis; (c) biologic evidence of a neurotropic strain of the treponema; (d) persistence of the infection *in loco*, as in aortitis, interstitial keratitis, etc.; (e) observation of patients who developed signs of early syphilis of the nervous system and who after many years died of paresis or other late degenerations; (f) no serologic evidence as yet exists showing normal spinal fluid in the early stage and its infection at a later period. 2. Early neurosyphilis may manifest itself by obtrusive symptoms by slight objective signs or be asymptomatic. Treatment by the usual channels may control the obtrusive symptoms. It seldom cures the underlying infection. Symptoms at times develop during or shortly after intensive courses of arsphenamin and mercury. If not cured these early infections may persist and cause late neurosyphilis. 3. Accept-

ance of the foregoing propositions leads to the logical deduction that no case of syphilis should be discharged without the knowledge gained by examination of the spinal fluid. In case no evidence of infection is found a prognosis of probable future immunity may be made. If infection exists it should be treated by methods shown by experience to be effective. 4. We are convinced by an experience of seven years in the use of intraspinal therapy that practically all cases of early neurosyphilis can be cured more rapidly, and in the majority of cases only cured, by the combined intravenous and intraspinal method.

5. Pulmonary Sequels of Influenza.—Maurice Fishberg finds that in many patients attacked by acute epidemic influenza certain sequels are left in the respiratory tract after the acute disease has run its course. A large number remain with subacute rhinopharyngitis, some with general bronchitis, and now and then one meets with patients in whom the residual lesion is a localized bronchitis. When the latter affects an upper lobe of a lung, it is very difficult to differentiate it from pulmonary tuberculosis. When these sequels are instrumental in keeping the patient weak and debilitated for weeks or months, which is often the case, this, in addition to the cough and expectoration, may lead to a diagnosis of pulmonary tuberculosis. More serious pulmonary lesions are bronchiectasis and lung abscess which have increased in frequency since the last pandemic of influenza. Bronchiectasis remains in cases in which influenza was complicated by pneumonia or pleurisy, or both. The diagnosis is at times very difficult mainly because of the ancient notion that influenza is a strong predisposing factor to tuberculosis. When the lesion is found strictly localized in one of the lower lobes of the lungs, and this is the case in the majority, tuberculosis should be excluded for this reason alone. In those in whom the lesion is in an upper lobe, only repeated sputum examination decides, though the fact that the disease began with influenza, that emaciation is not pronounced, that fever is lacking, the pulse-rate is normal, and that there is obtained clear resonance above the clavicle, etc., should be counted against tuberculosis. In the more severe lesions in which pulmonary abscess remains after influenza the diagnosis may be made along the same lines as in bronchiectasis, and in addition note should be made of the fact that the sputum is abundant, at times fetid, the fever continuous or undulating, the pain in the chest, and the physical signs, all of which combine to clear up the diagnosis. If several examinations of the sputum fail to disclose tubercle bacilli the diagnosis may be safely made. Leucocytosis, with an increased proportion of polynuclear cells, has the same significance.

8. A Record of Experience with Certain Physical Efficiency and Low Oxygen Tests.—Edward C. Schneider reports the results of a study of 128 aviators who were subjected to the Official Altitude Classification Examination used by the Air Service Section of the U. S. Army; to five of the standard respiratory tests used by the Royal Air Force in England, and to a careful overhaul by a neurologist, internist, ophthalmologist, and otologist. The clinical examinations showed thirty-one of these aviators to be stale or physically below par. From these studies the writer finds that certain criticisms may be offered against the simple respiratory tests. They require too much voluntary attention and hearty cooperation on the part of the patient. The results are not capable of physiological interpretation unless they represent the best effort the patient can put into each test. Indifferent subject and listless observer both vitiate the results. If the patient wishes a vacation, knowing that a poor showing in the tests indicates fatigue and need of a rest, he can easily imitate the "all-in" man. The tests are in some respects psychological, since if a man determines to hold his breath until discomfort is pronounced it can be done, or he may give up with the first feeling of effort. To sustain the mercury column in the "fatigue" test requires some skill, and a proper set of the lips may ease the performance so much that twenty or more seconds are added to the length of the hold. The expiratory force test, if well done, requires great effort and the height of the blow often depends upon the ability to coordinate the contraction of the chest and abdominal muscles. The coefficients of correlation for the power

of breath-holding, vital capacity, "fatigue" test, expiratory force and extrarespiratory reserve factor, with compensation to low oxygen, were found to be of such low value that the simple respiratory tests could not be accepted as aids in determining fitness for high altitude flying. The degree of physical fitness appearing as shown by an examination of thirty-one temporarily unfit men cannot be measured either by the simple respiratory tests or by the low oxygen of the re-breathing test. Seven men were able to improve their records in the respiratory tests by practice.

2. A Gospel of Error.—C. Edmund Kells, D.D.S., emphasized the following points: 1. A tooth with a devitalized pulp is not dead; it continues to be a vital tooth just so long as it receives nourishment from its periodontal membrane. 2. Alveolar abscess can be cured just as pneumonia or measles can be cured. 3. Teeth are a valuable asset; are necessary for mastication and from a cosmetic point of view. 4. A radiolucent area may be infected—it may be sterile. 5. Infection cannot be determined by the x-ray. 6. No one but a dentist should advise the extraction of a tooth. 7. It is true that "wonderful cures" have resulted from the extraction of some diseased teeth, but what of the countless thousands of good teeth extracted with no beneficial results following? Such being the facts in this "gospel of error," the thoughtful physician who has the welfare of his patients at heart will yet come to see that in order to render them the best services possible he must refer them to a dentist, and none other, for an oral diagnosis.

8. On the Importance of Muscular Relaxation in the Examination of Joints.—Carl Westman gives the following points as useful guides in testing muscular relaxation: 1. When the patient is lying on his back with his head rested, note the condition of the sternomastoids. If these stand out prominently—which they may very well do without the head being actually lifted, but which means that they are in active contraction—the muscles of the chest and abdomen also are more than likely to be in a state of tension. 2. If the muscles of the lower limbs are relaxed, these will be found to be more or less rotated outwards, this being their position of ease. Unless the patient is coaxed into this position, they will invariably be found held with the feet pointing vertically upwards, which means active contraction of the internal rotators of the femur. 3. The patella should be freely mobile; if it is not, it is a sign of active contraction of quadriceps femoris. 4. If the patient is being examined in prone position, with his head preferably resting on his hands, the relaxation of the glutei is a good indication of general muscular relaxation. These are particularly sensitive, any interference causing them to contract immediately, their flat appearance in relaxation changing into a bulky mass drawn up towards the middle

line. General muscular relaxation will be established in this manner in most cases. The local examination can then be proceeded with, unhampered by such contraction of surrounding muscles which is caused by "tension of mind" rather than any organic irritation. During the examination a careful watch should be kept on the muscles lest they should fall back into their tension state; as soon as this is evident, the movement of the joint should be stopped and the muscles again be coaxed into relaxation. Many stiff joints will thereby become freely mobile.

Mass Poisoning with Bread.—Silberschmidt refers to an episode of May, 1918, in the Canton of Zürich, in which 190 individuals were attacked at the same time with symptoms of poisoning, after having eaten of bread traced to one bakery. The date of the baking was May 22 and the deliveries were not made until three days later. The baker's wife was the first victim, she having fallen ill on the 27th. A few who ate of the bread were not affected (10 per cent). The symptoms were those of an irritant poison, such as vomiting and purging, and headache and vertigo were other complaints. The course was mild and the duration was from 1 to 4 days. Dogs and cats were made ill by feeding the bread to them, but small laboratory animals were immune. An aqueous extract of the bread caused a dog to vomit. Research for metallic poisons, alkaloids and other known toxic principles all ended negatively. It can only be surmised that in the course of fermentation a heat-stable toxic substance was formed. The flour and other ingredients were never under suspicion because the last baking before the accident had caused no disturbances. The same flour was extensively used in other bakeries. Its composition was wheat, 70 per cent., maize 20, rice flour 10.

Can Epidemic Encephalitis Cause True Parkinson's Disease?—Bing discusses this subject exhaustively. We may speak in this connection of "parkinsonism" in the sense that the syndrome is indistinguishable from that of paralysis agitans. Of cases given one was a perfect simulation of the typical disease. Only time can tell if it will prove to be such. The case has progressed for the worse and the so-called "pill-rolling" movement, or, as others call it, "money counting," was in evidence.

Le Bulletin Médical.

February 9-12, 1921, xxxv, 7.

Disjunction of the Pelvis in Equestrians.—Berard relates the following case. The subject was an unusually strong and vigorous man of 63 who was breaking in a young saddle horse, riding at the time without stirrups. His mount was refractory and he was hugging its flanks with his knees when a jolt from the animal was followed by the sensation of being cleft in two. He at once slipped to the ground where a severe pain low in the abdomen became manifest; and being unable to rise he had himself transported in a farmer's wagon to a doctor's office. The medical man saw his patient three hours after the accident and found him in partial shock. The least movement caused an intolerable pain in the left lower extremity. An intense desire to urinate was followed eventually by the passage of a little blood succeeded in turn by some clear urine. The pubes was found surrounded by a resistant tumefaction which extended as high as the umbilicus. Ether and caffeine were injected and followed by morphine and the patient transported to a hospital. Here the clothing was removed and the swelling was found to be still increasing in size, involving the scrotum and perineum, thighs, flanks, and hypogastrium. Only the penis and scrotum showed ecchymoses. A sound showed that the urethra and bladder were intact. The patient was treated for internal hemorrhage and shock, ergot being the only hemostatic. The author when called in found a diastasis of the pubic bones, confirmed next day by the x-ray. The hiatus was 6 cm. The left lower extremity was so sensitive to movement that the patient was kept immobilized for a fortnight. He was able to leave his bed after six weeks and went about on crutches. The separation was still 3 cm.

Book Reviews.

MODERN SURGERY: GENERAL AND OPERATIVE. By JOHN CHALMERS DACOSTA, M.D., LL.D., F.A.C.S., Samuel D. Gross Professor of Surgery, Jefferson Medical College, Philadelphia; Surgeon to the Jefferson Medical College Hospital; Consulting Surgeon to the Philadelphia General Hospital, St. Joseph's Hospital, and Misericordia Hospital, Philadelphia; Consulting Surgeon to the Hospital for the Insane, Eastern District of Pennsylvania, at Norristown; Fellow of the American Surgical Association; Member of the Society of Clinical Surgery; Member of the American Philosophical Society; Membre de la Société Internationale de Chirurgie; Commander, Medical Corps, U. S. N. R. F., etc., etc. Eighth Edition, Revised, Enlarged and Reset, with 1177 Illustrations, Some of Them in Colors. Philadelphia and London: W. B. Saunders Company, 1919.

A TEXTBOOK which has been a popular favorite for over twenty-five years, as shown by the fact that twenty-four reprintings as well as seven complete revisions have been necessary to keep pace with the demand and with the progress of surgery since the book was first copyrighted in 1894, hardly seems to need critical review, but, rather, merely a few words of introduction to the neophytes of the medical profession.

We now have a new revision, but one which was made under very adverse circumstances, since both the author and many of his assistants were engaged in war work here or abroad, and many very important sources of information were not available, particularly files of certain important medical journals. Still, it is apparent that considerable portions of the text have been entirely rewritten; and this applies particularly to those subjects in which methods of treatment have been markedly changed or revolutionized by the experience gained in the recent war.

All through the book changes of major or minor importance are to be noted, and it is safe to say that in most respects the book is thoroughly up to date. There are occasionally lapses as, for example, in the description of the Edebohl technique for nephropexy, which is far from that published and practised by Edebohl in the later years of his life; but in such cases it is only fair to assume that failure to correct the text was due to the difficulties in referring to the literature. Many of the illustrations, especially reproductions of photographs and radiographs, are very poor; and it is to be hoped that at the next revision this department will receive a thorough overhauling.

ORTHOPEDIC AND RECONSTRUCTION SURGERY, INDUSTRIAL AND CIVILIAN. By FRED H. ALBEE, A.B., M.D., F.A.C.S., Lieutenant-Colonel M.C., U.S.A. Professor and Director of the Department of Orthopedic Surgery at the New York Post-Graduate Medical School and at the University of Vermont; Chairman Rehabilitation Commission of State of New Jersey; Member of Advisory Orthopedic Council to the Surgeon General; Chief Surgeon U. S. Army General Hospital No. 3, Colonia, N. J.; Visiting Orthopedic Surgeon to the New York Post-Graduate Hospital and to the Blythedale Hospital, etc. Philadelphia and London: W. B. Saunders Company, 1919.

This is a monumental work, covering from all angles the subjects usually considered to belong to orthopedics and also many conditions originating in industrial work, while there are also about 100 pages devoted to military and reconstruction surgery. Among the author's reasons for combining the consideration of these various subjects in one book were: appeals from both graduate and undergraduate students for a book which should consider not only conservative methods, but also the well tried operative methods of treatment of bone and joint conditions, diseases and deformities; the tremendous influence which is being exerted upon surgical practice by the recent war and, to a slightly lesser extent, the effect upon traumatic surgery of Workmen's Compensation Laws; and the importance of combining in one treatise both the conservative and operative systems of treatment, thus demonstrating the interrelationships of the two and the mutual dependence of one upon the other. Since the author is particularly interested in the operative side, this has naturally re-

ceived special emphasis whenever justifiable, but he has covered all phases of his subject very exhaustively and well; and just as much stress has been laid upon conservative methods when they are indicated as upon the operative when, in his opinion, that is indicated. For those who may wish to pursue any individual subject further he has supplied a remarkably extensive bibliography.

The book is, however, not without its faults. The chapter headings seem to follow no orderly sequence, anatomical or otherwise, and a great many pages in the aggregate could have been saved without impairing the value of the book if the author's style were less prolix and if other writers' views were stated in substance instead of so often being quoted verbatim and *in extenso*. Some of the borderline conditions (those perhaps belonging more to general than to orthopedic surgery) would better have been omitted than so inadequately treated, as, for example thromboangiitis obliterans, an extremely important disease, which the author attempts to cover in ten lines. Many will say that the Albee bonegraft operation in all its various guises (inlay, dowel peg, etc.) is unduly emphasized, yet it is only natural that the author should recommend his own operation if he thinks it offers the best chance of cure.

A HANDBOOK OF MIDWIFERY. For Midwives, Maternity Nurses, and Obstetric Dressers. By COMYNS BERKELEY, M.A., M.C., M.D. Cantab., F.R.C.P. Lond., M.R.G.S. Eng.; Obstetric and Gynaecological Surgeon to the Middlesex Hospital; Lecturer on Midwifery at the Middlesex Hospital Medical School; Senior Obstetric Surgeon to the City of London Maternity Hospital; Surgeon to In-Patients at the Chelsea Hospital for Women; Examiner in Midwifery and Diseases of Women to the Universities of Oxford, Cambridge, London, Manchester and Sheffield, and Examiner to the Central Midwives Board; Sometime Examiner in Midwifery and Diseases of Women to the University of Leeds, the Conjoint Board of England, and the Society of Apothecaries, London. Fifth Edition, Enlarged. With Color Frontispiece and 74 Illustrations in the Text. New York: Paul B. Hoeber, 1921.

The purpose of this book is indicated by the title. It was drawn up to serve as a textbook for the examinations conducted by the Central Midwives Board, and it contains all that is necessary for that purpose. If a nurse or midwife has carefully studied this volume, she should be able to carry on her occupation with credit to herself and with safety to her patients. The book is very clearly written, and contains the necessary information on elementary physiology and anatomy, as well as on pregnancy, labor, the puerperium, a sepsis, preparation for obstetrical operations, and the care of the newborn child. Two things strike the reader of this volume, one is the absence of all unnecessary details—thus, there is no attempt to make an expert bacteriologist of the nurse or midwife; and the other is the very readable and clear statement of all that is really required. Thus the work is an ideal textbook. Further, it is of a handy size, it is well printed, and there are sufficient and serviceable illustrations.

STUDENTS' SYNOPSIS SERIES. PHARMACOLOGY. By DOUGLAS COW, M.D., Examiner in Pharmacology, University of Cambridge. With 15 Illustrations. London: J. and A. Churchill, 1920.

THIS is the first volume of a new series of compends. It is dedicated "to that great army of medical students, some eighty per cent. of the whole, who in examinations are within measurable distance of the rubicon that divides the approved from the rejected." On looking through the volume one is struck with the care with which the book has been compiled and also with the numerous omissions. It is true that what is omitted ought not to be required of students, but so long as examiners are what they are, so long will students have to load their memories with unnecessary preparations and doses. In preparing for a sensible examination in pharmacology, this book should be of very great value, but for the ordinary examination it will hardly suffice. The preface contains much matter for thought; and we would draw attention to the fact that the author of this work is a university examiner.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON SURGERY.

Stated Meeting, Held November 5, 1920.

DR. SEWARD ERDMAN IN THE CHAIR.

Bony Ankylosis of the Temporomandibular Articulation.—Dr. HENRY S. DUNNING presented this patient, in whom the ankylosis had been of long standing. A cure with good function was obtained by the excision of the upper one-third of the ramus.

Plastic Repair of the Angle of the Mouth: Loss of Tissue Occasioned by Noma Some Years Previously.—Dr. DUNNING presented this patient, a boy who had had noma at the angle of the mouth for which he received no treatment. The lesion healed after about six weeks but left a defect extending back $1\frac{1}{2}$ inches from the angle of the mouth on the left side. When he came under Dr. Dunning's care his cheek was absolutely adherent to the buccal mucous membrane. At the first operation the adherent tissues were freed and a model was taken of the defect to be filled. A skin graft was introduced from the leg, which later sloughed out and the condition reverted to its former state. He then tried a pedunculated flap of skin with subcutaneous tissue cut from the patient's neck. This flap was applied so as to provide a mucous lining and to fill in the defect. This flap also partially sloughed out. Finally the thinned out remaining portion of the flap was placed so that it gave both a lining for the mouth and a skin surface, and a fairly good cosmetic result was obtained.

Dr. ROBERT T. MORRIS said that in a case of bony ankylosis of the jaw of the ordinary sort the patient might escape with a mild attack of surgery if he used a narrow sharp chisel and divided the bone just below the point of ankylosis. He did this as a preliminary step and sometimes it gave a mobile fibrous union. One could round off the bone ends through a small incision and with little danger to the parotid gland and facial nerve. This could sometimes be done in the ordinary case reserving excision for a later step. Dr. Dunning's case, however, was unusual in that the ankylosis was much more extensive than in most cases.

Dr. EDWARD WALLACE LEE congratulated Dr. Dunning on his very satisfactory result. He said he had seen this case through the process of repair and he thought the result obtained was very wonderful. He did not think Dr. Dunning was going to get such an excellent result. The ordinary operation—Murphy's operation for ankylosis of the jaw—was a very simple procedure compared to an operation of this sort. In the Murphy operation muscle was simply transplanted to prevent a bony adhesion and then passive motion was begun to prevent further ankylosis.

Dr. CHARLES E. FARR asked whether in the second case there was much suppuration in the flap and whether there was sloughing. He said he had had a case some ten years ago in which there was suppuration which produced scar tissue and that this had helped in the end result.

Dr. L. T. LEWALD said he was much interested in this case as he had seen it from the start and could vouch for the completeness of the ankylosis. It was difficult at first to tell on which side the ankylosis occurred. At first glance it was not easy to tell even from the radiograph which side was ankylosed, but by study of the plates taken in the mastoid position one was convinced that there was complete bony ankylosis on one side while on the opposite side there was a fine line showing fibro-cartilage. The immediate and prompt opening of the mouth after the operation was most striking and showed the wisdom of taking out a large section of bone as was shown in the radiograph. The condyle of the ramus was rounded off so that it offered no chance for reunion of the bony surfaces, and thus a permanent cure was assured.

Dr. SEWARD ERDMAN thought the case was interesting because it showed that immobilization of a normal joint even over a long period of time did not result in ankylosis. The fact that the normal side of the jaw

which was immobilized for so many years had not ankylosed afforded evidence that ankylosis was more a matter of changes in the muscles and soft parts than in the bone itself. It was certainly of interest that after twelve years of immobilization and complete locking of the jaw there should be no ankylosis.

Dr. LEE asked how Dr. Dunning determined that there was unilateral ankylosis. How was one going to tell when a patient came with a bony ankylosis of the jaw on which side the lesion was situated?

Dr. LEWALD replied that the radiograph did show on which side the ankylosis was situated. Without the x-ray it would have been extremely difficult to decide. The x-ray evidence, however, was absolute. Prolonged and extensive ankylosis on the one side had not resulted in any ankylosis on the opposite side.

Retrocecal Traumatic Appendicitis.—Dr. A. L. SORESI presented this case. A boy 11 years of age was brought into his service at the Greenpoint Hospital, complaining of pain on the lower right abdominal side following an accident. Patient had been struck by a plank. The exact point where he had been struck could not be determined, as there was no abrasion or any other mark on the skin, but it was judged to have been about an inch above the superior anterior iliac spine. Immediately following the accident he suffered very severe pain, was taken home and placed in bed; pain subsided in a couple of hours, and the two days following he was able to walk about the house, feeling only slight pain in the abdomen, with no rise of temperature or nausea. Two days after the accident pain became much sharper, physic was administered, and a physician called. The boy was sent to Greenpoint Hospital with the diagnosis of appendicitis. On admission the blood count showed 12,000 leucocytes, 75 per cent. polymorphonuclears; there was no temperature and only slight nausea. Pain was present on pressure on a point about two inches above the anterior superior iliac spine externally to the rectus muscle. The patient was put at rest in bed on fluid diet. On the second day after admission to the hospital a slight rise of temperature occurred, but the bowels had not moved, and following an enema the temperature again became normal. Blood count showed 6,200 leucocytes, 60 per cent. polymorphonuclears. Seven days after admission he began to run a slight temperature indicative of sepsis and operation was decided on. The blood count showed leucocytes 28,000, polymorphonuclears 87 per cent. On opening the abdomen by a right pararectal incision the abdominal organs appeared absolutely normal, but on passing the finger around the external border of the cecum some fluctuation could be felt. The abdominal cavity was packed and the cecum freed externally, and about an ounce of thick foul-smelling pus was found to be present, in which two scabiae were found. There was no trace of the appendix except a great amount of tissue debris, and a large hole in the cecum. The pus extended almost to the hepatic flexure. After cleaning well the cavity with sponges and ether, the tip of the appendix was found and partly removed. The hole in the gut was sutured, not very tightly on account of the friability of the wall of the cecum, the cavity drained with a paraffin drain brought out through the posterior abdominal wall, and the cecum allowed to drop into its place. The abdominal wall was closed with two rows of catgut sutures, the skin with elastic bands; the abdominal incision was drained by a separate stab wound and paraffin drainage. On the third day a small amount of feces escaped from the posterior drain and continued for three days. As was shown, the patient was still draining slightly after fourteen days, but only through the posterior stab wound. The abdominal incision was healed beautifully by first intention. The case presented was a real traumatic retrocecal appendicitis, and its etiology could be explained in the following manner: The plank, striking the abdominal wall, tore the appendix from its meso; some reaction followed; then things subsided until the appendix, deprived of its blood supply, began to slough off and give rise to the symptoms which led to the operation.

A Safe and Simple Method for the Extirpation of the Adherent Retrocecal Appendix.—Dr. WILLY MEYER made this presentation. He stated that the proportion of polymorphonuclear leucocytes afforded a good basis

for prognosis in both acute and chronic appendicitis. In both of these types of appendicitis the sooner the appendix was removed the better for the patient, for the appendix once diseased seldom returned to normal. The first attack of appendicitis did not mark the beginning of disease, but was merely the explosion of long stored up and easily inflammable material. It was impossible to say who would be so fortunate as to escape a second attack, and when there was a severe attack immediate operation was required. Twenty-five years ago he had given the dictum that the appendix should be extirpated after the first attack and this still held good. The mortality of acute appendicitis operated upon during the first twenty to twenty-four hours was practically nil. Operation was less dangerous than delay. As to the operation itself, opening the abdomen by blunt division of the rectus muscle gave every assurance that the abdominal wall would be as strong after as before operation. Some questions with reference to appendicitis were still unanswered. First among these was that of etiology, the relation of appendicitis to duodenal and gastric ulcer, and the relation of a high retrocecal appendix to appendicitis. Dr. Meyer made a comparison of the various incisions used in appendectomy and expressed his preference for the pararectal incision. If the appendix was situated retroceally he then added an incision higher up and posteriorly, along the crest of the ilium, and one-half inch from the crest of the ilium. One could spread the fibers of the external oblique and cut the fibers of the internal oblique near the crest of the ilium without injury to the ilioinguinal and iliohypogastric nerves, and by retracting the muscles inward one could enter the abdominal cavity. Through this incision the regions high up in the abdomen, and even beneath the liver, could be made accessible to the surgeon's eye. Dr. Meyer presented a patient in whom he had used this incision after finding the appendix inaccessible through the pararectal incision, and also gave a lantern slide demonstration.

Dr. A. L. SORESI said the point brought out by Dr. Meyer was that it is difficult to remove an appendix which is retrocecal through the ordinary incision. Dr. Soresi showed with lantern slides that it was easy to remove an appendix, even when it was retrocecal—as in the case presented before the Society—if the technique seemed to be more efficient than the one recommended was followed; this technique seemed to be more efficient than the one recommended by Dr. Meyer, as it did not require a new incision, which might at least be the cause of hernia. The main point of the technique recommended by Dr. Soresi was that the incision should be pararectal, and retraction should be made only externally, so as to expose the ascending colon and the cecum and never to do any work in the abdominal cavity, but always to the right of the cecum; by this method the whole procedure was practically extraperitoneal. The second point was that the surgeon should never look for the tip of the appendix, as its position was variable, but look always for its base, which was a well fixed point. The base of the appendix could always be found in all cases, if retraction was made on the external border of the abdominal incision; then the cecum was raised, and if necessary, as when the appendix was completely retrocecal and might reach the hepatic flexure—as in the case presented—the ascending colon was dissected from the parietal peritoneum, as was done in removal of the colon, so that the blood supply of the cecum and its normal physiological position were not disturbed. Then the appendix was caught at its base, a purse-string suture applied, and the stump of the base inverted without tying it, because by tying and inverting it a closed pocket was formed. However, the suture must penetrate all the coats of the intestine in order to prevent post-operative hemorrhage. The main point to remember was that in all cases of appendicitis the most important part of the operation was the securing of the base of the appendix, so that the intestinal contents could not leak into the abdominal cavity. When the appendix could not be removed *in toto*, there was no danger in leaving the tip, because the tip of the appendix, deprived of its blood supply, would slough off, and to prevent any danger it was only necessary to supply adequate drainage; on the contrary, if the base of the appendix was not prop-

erly secured, serious troubles might ensue, the least being the formation of a fecal fistula. In all cases where drainage was required, it should be made posteriorly through a separate stab wound, and paraffin drainage should be used, because it really drained and could not cause irritation or trauma, and allowed a firm union of the laparotomy incision, so preventing hernia. The abdominal wall along the surgical incision always had to be drained in order to prevent post-operative hernia. The drainage must be made with paraffin drains brought through a small separate incision, so that if suppuration occurred the incised tissues would not split open. If proper paraffin drainage was provided, and the skin was closed as demonstrated by elastic bands, healing by first intention was practically certain, even when suppuration took place, as in the case presented to the Society.

Dr. NATHAN W. GREEN said that when he heard that Dr. Meyer was going to read this paper on the modification of the incisions used in appendicitis he was delighted, and had come to hear Dr. Meyer and to discuss the procedure. Dr. Meyer had spoken to him of this modification some four or five years ago, and he had taken the opportunity to work it out in the dissecting room to see just how he continued his incision upward and outward along the crest of the ilium. One could extend this incision upward and outward between the fibers of the external oblique clear to the border of the ribs if necessary. One could then spread the fibers of the external oblique and cut the fibers of the internal oblique near the crest of the ilium without injuring the ilioinguinal and iliohypogastric nerves, provided one made the incision through the transversalis about one-half inch from the crest of the ilium. (The deep circumflex iliac artery lay next to the crest.) If the muscles were then retracted inward one could enter the abdominal cavity without affecting the nerves. This patient whom Dr. Meyer had presented had perfectly hard muscles, showing that the innervation had not been injured. It was a nice thing to know in doing an emergency operation for appendicitis that one could make this incision parallel to the crest of the ilium and carry it back as far as the middle of the crest and could then rotate the cecum inward and get at a retrocecal appendix satisfactorily. And it was also reassuring to know that one could suture the deep muscles and have their function preserved, and know that one would not get a hernia afterward. Dr. Green said he had used this incision, found it highly satisfactory, and thought it should bear Dr. Meyer's name, just as Dr. Wier's extension to the McBurney incision had his name attached to it.

Dr. EDWARD WALLACE LEE said he simply wanted to emphasize one of the points that Dr. Meyer had already emphasized, namely, that we should all be more particular in the diagnosis of appendicitis. We should try to make a more definite localization as to where the diseased appendix was. Dr. Meyer's illustrations emphasized that point. Dr. Lee said that very often one found, or at least he found, that one easily fell into the habit of thinking that it was easy to diagnose acute appendicitis and then to go in and operate in a stereotyped way without giving due consideration to the point that had just been brought out. The incision should be regulated according to the pathology that existed inside, and we should be more careful to determine what that pathology was and where it was. He was glad to hear Dr. Meyer bring out this point. Dr. Lee said he was Dr. Meyer's senior in operating on appendicitis cases. He had operated in May, 1884, four years before Dr. Meyer began to perform the operation. His first case of appendicitis was that of a patient with a lump in the right side which he diagnosed as perityphlitic abscess, and when he opened it the sloughed off appendix came out. This was in the day when appendectomy was little heard of.

Dr. ROBERT T. MORRIS expressed the opinion that Dr. Meyer had made a definite contribution to surgery which was of special value in cases in which there was defective rotation of the colon and the appendix was located retroceally, if he could suture these muscles so that they gave firm union subsequently. The physics involved included the idea that the three muscles had three lines of traction, hence it was important to suture each muscle separately. If he was able to do that he

had made an important contribution to the subject. If one had his gloves off it did not make a great deal of difference where the appendix was if the cecum was in the normal position. Dr. Sorens had brought out the point that in 50 cases of appendicitis with abscess he had had primary union where he had used the paraffin drain. That was a good thing, but the paraffin drain was not the cause of the primary union in those 50 cases. The reason he had primary union in these cases was because the pus was often sterile or nearly so. This was due to the fact that bacteria worked in the tissues rather than in pus. In pus they were often disabled by enzymes or their own by-products, and rendered latent. One frequently obtained primary union even though the wound was bathed in pus. This was a statement which would have caused an explosion a few years ago, but the subject was now so well understood that the experience of Dr. Sorens did not even lead to much comment.

Dr. W. H. STEWART said that he would like to call attention to the importance of being able to recognize a retrocecal appendix by means of the x-ray examination. One could locate the appendix by a careful and repeated fluoroscopic examination covering a period of 72 hours. The retrocecal appendix was especially recognized as the cecum emptied. The importance of such a localization would seem to the speaker as a very vital point, particularly if one was to adopt the incision of Dr. Meyer. If the appendix was known to be in a retrocecal position, only one incision would be necessary. The matter had been brought closely home to the speaker in the case of a member of his family who had repeated attacks of appendicitis. He had examined him roentgenographically and had located the appendix retroceally. Irrespective of his findings, a surgeon made the McBurney incision. He found the appendix deeply imbedded behind the cecum; instead of making a second incision as Dr. Meyer had advocated, the McBurney incision was enlarged to such an extent that the boy to-day was suffering from a hernia. The speaker thought that the fact that it was possible to locate the retrocecal appendix by the x-ray, should be brought to the attention of the medical profession that they might avail themselves of its use in chronic appendicitis.

Dr. L. T. LEWALD asked Dr. Meyer if he believed that non-rotation of the colon or incomplete fixation predisposed to appendicitis. Dr. Dudley Roberts read a paper before the section last spring, in which he made the statement that non-rotation of the colon predisposed to appendicitis. Dr. LeWald said he had known of a number of cases of non-rotation of the colon that were not associated with appendicitis. A few days ago Dr. Downes had told him of a case in which non-rotation of the colon was associated with appendicitis, and five such cases were reported from the Mayo Clinic. He would like to know whether this was simply a coincidence or whether a non-rotated colon afforded some inducement to appendicitis.

Dr. MEYER, in closing the discussion, said if he understood Dr. Sorens correctly he thought the diagnosis of retrocecal appendix was difficult. It was not difficult, particularly in acute appendicitis, with the exception of one condition, and that was if the appendix was covered with omentum; then, of course, the parietal peritoneum could not become so quickly inflamed and consequently the tenderness at first would be reduced or missing. In the acute appendix one would find the McBurney point tender in almost every instance; if exceptionally it was not tender one might find tenderness along the crest of the ilium. With this finding, particularly if there was a high polynuclear count, the diagnosis of the acutely inflamed retrocecal appendix was quite certain. The diagnosis of chronic appendicitis in a retrocecal appendix was more difficult, but frequently following an attack there was also a point of tenderness posteriorly. Dr. Sorens had further spoken of cutting along the outer side of the ascending colon if the appendix was not found in the normal situation. Opening the retrocecal space one might find the appendix in that way, but it was not best for the patient to do so. In acute appendicitis, particularly with a gangrenous appendix, this procedure was not to be compared with that of remaining within the focus of infection instead of opening new lymph

spaces for absorption. If the appendix was short it might of course be taken out through any kind of incision, but if it was long or rotation of the cecum had not taken place a longer incision upward would be necessary, or the second posterior incision as he had just described. He did not consider it wise to leave a portion of the appendix behind. In answer to Dr. LeWald's question, he thought it must be that non-rotation of the colon and cecum would have a tendency to produce appendicitis. He had not the slightest doubt but that a non-rotated colon and cecum predisposed to appendicitis.

Late Results of Tonsillectomy.—Dr. JOHN A. VIETOR presented this contribution, which consisted in a statistical report of 500 cases of tonsils and adenoids operated upon by the Second Surgical Division of the New York Hospital from April 1, 1915, to October 1, 1919. The end results were arrived at through the Follow-up Clinic, where the patients were personally seen by one of the attending surgeons. On each return to the Follow-up Clinic a careful history was taken, emphasis being laid on the gain or loss in weight and strength; occurrence or frequency of sore throats; change in breathing voice or hearing. The patient was then examined by one of the attending surgeons and notations were made of any remaining tonsillar tissue, the condition of the pillars, fauces and uvula. The presence or absence of ear discharge was looked for. The result at each examination was put down, but not classed as an end or final result until the patient was discharged from the Follow-up Clinic. This tentative result was classified under two headings: "The Anatomical Result" and the "Symptomatic Result." Under each heading the net results were classified as "Good, fair, or poor." A patient might have a good symptomatic result and a poor anatomical result. Of the total 500 cases, 394, or 79 per cent., had been followed for an average period of 5½ months; 106 cases, or 21 per cent., were lost sight of, or were based solely upon the reports of the social service nurse. Of the 394 cases 327, or 83 per cent., were children referred to the service by local school board or public health officers for frequent sore throats, faulty breathing, or simple hypertrophy. The remaining 44 cases were admitted for other complaints. In 26 cases the tonsils were hypertrophied and were removed as a prophylactic measure at the time of an operation performed for an independent condition such as circumcision, hernia, chronic appendicitis, and Pott's fracture. There were 18 cases in which the tonsils and adenoids were a contributory or etiological factor. These included 8 cases of tubercular lymph nodes, 3 of arthritis of the knee, 2 of chronic valvular disease, 2 of chorea, and 3 of chronic otitis media. Of the 394 cases followed, 97 per cent. were reported symptomatically good and 3 per cent. as fair. Anatomically, the results were 84 per cent. good, 10 per cent. fair and 6 per cent. poor. The author analyzed these results in detail, stating in the course of his analysis that the two cases of chronic valvular disease were not benefited by the operation, while chronic otitis media afforded a brilliant field for adenoidectomy. The routine treatment was practically the same in all tonsil cases. A complete physical examination, including a urine examination, and in children a Schick test, was made on admission. The operation was performed in the operating room under a general anesthetic (nitrous oxide gas and ether) with only two exceptions. No operations were done in the out-patient department, as that procedure was considered unsafe and dangerous on account of the subsequent bleeding and danger of infection in an open throat. The tonsils were enucleated with instruments instead of by the fingers, the Rose position combined with the Ilitz mouth gag and the Pool and Kemyon aspirator with a specially designed suction tip, being used to get the best exposure and protect the patient from the aspiration of blood, mucous, and pus. After operation the patients were put to bed, kept quiet, and watched for any undue hemorrhage. Children were kept in bed a day longer than adults. The writer then considered the early and late complications, the former being hemorrhage, 5 cases; lobar pneumonia, 1; abscess of neck, 1; diphtheria, 1, and acute mastoiditis, 1 case. After discussing these complications in detail the author concluded as follows: (1) Ton-

sillotomy and adenoidectomy in well-chosen cases, performed by general surgeons, in a general service, under proper conditions, shows 97 per cent. symptomatically good results. (2) The complications arising either early or late were few, and not severe in character. (3) The benefits arising both in simple cases and in those in which tonsils act as a portal of entry, warrant their removal. (4) The dangers of the operation are almost nil, as shown by the fact that there were no deaths due directly or indirectly to the operation in this series of 500 consecutive cases.

Dr. EDWARD C. BRENNER commended the paper and said he was very glad to hear Dr. Victor say that the patients came into the hospital the night before and were given a complete physical examination before being operated upon. He presumed they also took throat cultures. He did not recall having heard Dr. Victor mention the indications for tonsillectomy, but supposed the children were referred mostly from the schools. One fact often overlooked in delicate children was that if the tonsils were affected the carotid chain of lymph nodes was also involved, and in these cases the lymph nodes usually diminished in size following tonsillectomy. The 97 per cent. of symptomatic cures was very high, but apparently this series had very few symptoms. Patients who had recurrent sore throat following tonsillectomy were usually those in whom tonsillectomy and not tonsillectomy had been performed. The recurrence of sore throat was usually evidence of an incomplete operation. As to the prognosis following tonsillectomy, in about 80 per cent. one might expect joint symptoms to be relieved. If there was pain in the muscles as torticollis, or growing pains, these symptoms were relieved in about 50 per cent. of the cases. If the glands of the carotid chain were tuberculous, and the tonsils were removed, the chronic tuberculous condition would remain. Until a few years ago it was not customary to operate upon children under three or four years of age, but now we were coming more and more frequently to operate on children at an earlier age if the tonsils were distinctly diseased, as shown by cervical adenopathy. Dr. Victor stated that in his series 10 per cent. gave poor results, 6 per cent. fair results, and 84 per cent. satisfactory results. These were good results, but not ideal. He stated that the Rose position and aspiration with sucker were used and gave the impression that this snare was a very bloody procedure. He had used the snare for three or four years, then finger enucleation, then the Sluder operation, and finally came to the Beck-Müller. He had tried practically all the procedures and preferred the Beck-Müller, even for small, contracted and buried tonsils. By this method both tonsils could be removed simultaneously, and it was practically a bloodless operation; one could see the tonsillar fossa bare with only slight oozing. This operation did not require artificial illumination, and many patients did not have even a sore throat the next day. The technique was easily mastered, and if general surgeons would perfect themselves in its use the results would be excellent and the imical criticisms now sometimes indulged in by the nose and throat men would no longer be justifiable.

Dr. WILLY MEYER said he was greatly interested in hearing that the surgical division of the New York Hospital was doing tonsillectomies, because in many hospitals this work was entirely in the hands of the specialists. Of course, all specialties were branches of general surgery. The follow-up system of the New York Hospital showed that they were fortunate in this series in having no case of aspiration of blood with its terrible consequences. Anyone interested in lung surgery knew that some of these patients aspirated blood during the operation, and that later the condition of bronchiectasis set in. All knew it to be a fact that a foreign body, hard, soft, or fluid, aspirated into the bronchus usually caused suppuration in the respective lung lobe that belonged to the bronchus in which the foreign body was lodged. It was much worse if liquids were aspirated, and these might be infected water, pus, stomach contents and blood. He knew of three cases of lung abscess perhaps belonging to the bronchiectases occurring in boys who had gone swimming in the waters around our metropolis, the pus showing the colon bacillus in pure culture. Our

wonderful city, that spent almost four hundred million dollars a year, still followed the old system of draining its sewage directly into the surrounding waters. The Health Board had often issued an order that there should be no swimming in these waters. It was regrettable that a city like New York should dispose of its drainage in this way instead of by a proper modern sewage system. In performing tonsillectomy, with the proper posture and aspiration with the electric aspirator, the surgeon could keep the operative field perfectly dry and avoid aspiration of blood and mucus as well as particles of the tonsillar tissue. Those who saw these cases of lung abscess, or rather bronchiectasis found that they gave a history of having been perfectly healthy until the time when tonsillectomy was done. Not long after they became seriously sick. The condition resulting was not curable except by a serious operation, lobectomy, which still gave a mortality of over 50 per cent. Dr. Meyer asked whether at the New York Hospital tonsillectomies were also done under local anesthesia. He knew of surgeons who did a beautiful tonsillectomy with the patient under local anesthesia, and the loss of blood was not more than one-half to one teaspoonful of blood.

Dr. L. M. HURD stated that the specialists were using general anesthesia in the removal of the tonsils in children and local anesthesia for adults. With the local anesthesia in adults they did away with aspiration pneumonia and lung abscess, and the mortality and morbidity under local anesthesia was less. That point was now being worked up by a committee of the American Medical Association. Tonsillectomy in the adult under local anesthesia was nearly always bloodless. The patient was given hyoscine and morphine as a preliminary. In reference to the Sluder and Sluder-Beck operations the speaker said he could not say that one method was more likely to be bloodless than another. One had hemorrhage with any operation at times. The results reported by Dr. Victor were good, and compared favorably with those of other hospitals, including the special hospitals. The symptomatic results were certainly first class. A very instructive paper had been published by Dr. St. Lawrence in the October 16 issue of the *Journal of the American Medical Association*. It showed 85 cases followed 3½ years, mostly rheumatic cases, and some heart cases. One point brought out by this report was that in 22 cases a clean operation was not done at the first operation. He did not know whether these operations were done at one clinic and by one man or at different places and by different operators, but they should have 100 per cent. clean dissections. Occasionally following tonsillectomy in a child there would be a strong effort to reproduce lymphoid tissue, but the older the child the less likely was this to occur, and the adult never reproduced lymphoid tissue following tonsillectomy. In children with toxic heart lesions it was only by destruction of the lymphoid follicles that the heart trouble could be relieved.

Dr. WILLIAM ST. LAWRENCE said that, as reference had been made to his recently published paper, he would be glad to answer the questions asked. He believed that final judgment upon the success of a tonsillectomy as to the physical removal of the tonsils, varied largely with the standard adopted. If to be successful, the tonsillar fossae must be absolutely free from tabs or lichen-like plaques of tonsil tissue, the operation could have been called successful in less than 60 per cent. of the cases in his series. In 22 per cent. of the cases the amount of tonsil tissue remaining was so great that the operation had been a failure from the standpoint of the focal infection and another attempt at removal was indicated. He felt that he owed it to the men at his own hospital to make quite clear the fact that the operations in the 22 per cent. of cases mentioned were not performed by them. These operations had been performed at both general and special hospitals throughout the city. At St. Luke's Hospital, the pediatricists' attitude was appreciated, and splendid co-operation was rendered by the nose and throat department. Dr. St. Lawrence said that he regretted that Dr. Victor had not presented the rheumatic and chorea cases in greater detail, for there are not nearly enough carefully studied cases in the literature.

Dr. MEYER spoke of the case of a lady with a soprano

voice who had a bilateral chronic recurring tonsillitis, and said he would like to know whether removal of the tonsils in such a case would interfere with her voice and prevent her from reaching the high "C." It would be a great favor to this woman to know that she could have her tonsils removed without interfering with her singing voice. He would like to know whether any observations had been made on this point by those present.

Dr. L. T. LEWALD emphasized what Dr. Meyer said about lung abscess. He said the roentgenologist saw these cases of lung abscess as well as the thoracic surgeon. He had seen four cases of lung abscess within the last year, and he had seen an operation done that afternoon by Dr. Howard Lilienthal. In this case there was no doubt that the abscess or the lung followed tonsillectomy. It started about the sixth day following the tonsillectomy, which was rather early. At the end of two years the man still had a bronchiectatic condition and a small cavity. A lobectomy had been thought of, but it was decided to do a compression according to Dr. Lilienthal's method. He recalled another case in an adult which ended fatally, so lung abscess was a complication of tonsillectomy that it was well to bear in mind.

Dr. BRENNER said he would like to reply to Dr. Meyer's question. Some time ago he had asked Dr. Alexander who was associated with the late Dr. Holbrook Curtis what the effect of tonsillectomy was upon the singing voice. Dr. Alexander assured him that the voice was not altered if the person was past puberty. If, however, the person had not reached puberty the voice might be affected. In adults in whom a faulty technic was employed with scarring of the pillars with subsequent scar contraction distorting the uvula and soft palate, occasionally a change in voice did occur.

Dr. VIETOR, replying to Dr. Brenner's question with reference to contraindications, said a culture of the throat was always taken and a positive culture was considered a contraindication. In the paper he had mentioned that an acute abscess did occur in one case. The average age of all cases was about 10 years. In regard to Dr. Meyer's question whether any of these operations were performed under local anesthesia, there were only two cases operated upon under local anesthesia, both by Dr. Erskine, who was a specialist, and operated upon other cases at the hospital not coming under this series.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

OHIO STATE BOARD OF MEDICAL EXAMINERS.

Columbus, December 1-3, 1920.

(Continued from page 636.)

DIAGNOSIS.

1. Name five endocrine organs. Give cardinal symptoms of diseases occurring in four.
2. Describe two diastolic murmurs. What is the prognosis for duration of fairly active life in each?
3. State the typical blood-findings in myelogenous leucemia.
4. What four signs suggest and what evidence proves the presence of fluid in the chest?
5. Describe urinary findings and symptomatology in two types of nephritis.
6. How differentiate between scarlet fever and measles on the first day a rash appears?
7. Differentiate cancer of the rectum from other conditions simulating it.
8. How confirm a diagnosis of diphtheria? Be precise.
9. Name five characteristic signs in various syphilitic diseases.
10. Differentiate dementia paralytica from senile dementia.

PATHOLOGY—BACTERIOLOGY—PUBLIC HEALTH

AND HYGIENE.

1. Describe the repair of bones after fracture, with explanation of reasons for faulty union in some instances.

2. Give the etiology and pathology of aneurysm of the aorta.

3. Explain the possible relation between abscesses of the teeth and some forms of arthritis.

4. What pathological conditions are included in the term "organic heart disease?"

5. Give the proper method of obtaining a specimen of suspected tuberculosis sputum. How would you send it through the mails to a laboratory, and give technique of laboratory examination?

6. Describe the colon bacillus. How isolate it? When may it be pathogenic?

7. What organisms are sometimes found in the spinal fluid? How would you identify them?

8. Name the requirements for an acceptable drinking water.

9. Mention some "industrial diseases" directly dependent upon improper working conditions.

10. Outline the objects of school inspection.

ANSWERS.

DIAGNOSIS

1. *Five endocrine organs:*—Thyroid, parathyroids, thymus, pituitary, and suprarenals.

Cardinal symptoms of Addison's disease:—Extreme weakness, loss of appetite, nausea, vomiting, bronzing of skin, low blood pressure, with feeble pulse.

Hyperthyroidism:—Rapid and often irregular pulse; nervous and psychical excitation, with muscular tremors; a feeling of warmth in the skin, and throbbing of cutaneous vessels, often accompanied by profuse sweating; shallow respiration; markedly increased metabolism (especially nitrogenous), with abnormal appetite and loss of body fat; a decreased assimilatory power for carbohydrates; an anxious, restless expression; prominence of the eyeballs; wide palpebral aperture, often with dilatation of pupils. The enlargement of the thyroid may involve only one lobe. (From Schäfer.)

Disease or removal of (two of) the parathyroids is followed by tetany, and wasting.

In *Acromegaly*:—"The face is egg-shaped, with its broad end downwards; the lower jaw-bone particularly is much increased in size, and may cause the lower teeth, which are wide apart, to project in front of the upper; the tongue is considerably enlarged, and this may cause a similar leathery speech to that of myxedema. The eyelids and nose are thickened and the ears hypertrophied. The extremities are markedly altered, the hands being huge and spade-shaped, and the nails broad and large. The feet show similar abnormal overgrowth, but the hypertrophy does not extend beyond the wrists and ankles, the long bones being but slightly affected. Later, the spine may become kyphotic, and the simultaneous prominence of the abdomen causes a characteristic "double hump." The ribs and sternum are also thickened. There is much general lassitude and weakness, and usually marked headache and anemia." (Wheeler and Jack's *Handbook of Medicine*.)

2. *TWO DIASTOLIC MURMURS.* In *aortic regurgitation*, there is a soft, blowing, diastolic murmur, heard over the aortic area to the left of the sternum, and transmitted down the sternum. The prognosis is variable; this is the lesion in which sudden death is most apt to occur.

In *pulmonary regurgitation* there is a diastolic murmur, which is generally loud and blowing and is heard most distinctly at the junction of the third left costal cartilage with the sternum; it is said to be transmitted along the left pulmonary artery. The prognosis depends upon the cause of the cardiac condition.

3. In *myelogenous leucemia*, the blood shows a permanent increase in the leucocytes other than the polymorphonuclear variety; myelocytes are present in great numbers, constituting from 20 to 60 per cent. of all leucocytes. The total number is about 300,000 per cubic millimeter as an average, but counts as high as 750,000 have been reported. The number, however, may be as low as 100,000 or even in some the count may approximate the normal. The differential count of the white cells in combination with the usual increase in number is the characteristic feature. The

main form is the large mononuclear myelocyte containing neutrophilic granules. They may constitute some 35 per cent. of all the leucocytes. The nucleus is situated, as a rule, in the center and is well staining, it may be eccentric, however, or poorly staining. The large cell with the pale nucleus is seldom found in any other condition than in this form of leucemia. The neutrophilic granules may be lacking entirely and the nuclei show hydropic degeneration. Occasionally small myelocytes with deeply staining nuclei may be present. Eosinophilic myelocytes may be found in large numbers, varying from 3,000 to 100,000 per cubic millimeter. Such an increase is pathognomonic of splenomyelogenous leucemia. The ordinary type of eosinophiles is also increased. Basophiles or mast-cells are increased, sometimes very markedly, this condition being quite characteristic of leucemia. Polymorphonuclear neutrophilic leucocytes are relatively diminished as the myelocytes increase, and form about 46 per cent. of the total. They are absolutely increased to 60,000 or 70,000. Degenerative changes are very common, the cells becoming more cohesive, the nuclei pale and showing karyolysis or rhexis and frequently mitotic figures. Lymphocytes are not very numerous as a rule; they constitute about 10 per cent., although the number may vary considerably. The blood itself may be pale and the specific gravity lowered. Coagulation takes place slowly. The erythrocytes are decreased to about 3,000,000, the hemoglobin is diminished also, 40 per cent., color index about 0.6. Many of them are nucleated and show changes in size and shape. The normoblasts are very common, and megakaryoblasts are frequently seen." (McConnell's Pathology).

4. *Four signs of fluid in the chest:* (1) Obliteration or bulging of the intercostal spaces; (2) vocal fremitus is diminished or absent; (3) dullness on percussion, the border of which varies according to the position of the patient; (4) Skodiak resonance above the border of the fluid, posteriorly. The presence of fluid in the chest is proved by tapping with a needle or trocar and cannula and drawing off some of the fluid.

5.

ACUTE PARENCHYMATOUS NEPHRITIS.

1. Most common in children, from exposure or infectious fevers.
2. Edema of lower eyelids; then of upper extremities, trunk, and, lastly, lower extremities.
3. Urine scanty, dark or smoky color, high specific gravity, 1025 or over.
4. Large amount of albumin.
5. Variety of casts, such as hyaline, blood, epithelial, and waxy casts, also free red blood globules, and epithelial cells.
6. Urea diminished.
7. Recoveries frequent.

CHRONIC PARENCHYMATOUS NEPHRITIS.

1. Later life; often the consequence of acute attack.
2. In early stage same as acute form; later, dropsy may diminish.
3. Urine normal or increased amount; specific gravity may fall to 1010; urine pale.
4. Late in attack, fremitus diminished; occasionally absent.
5. Large and small granular casts; compound granule cells, and fatty epithelium.
6. Urea diminished.
7. Recoveries rare.

(From *Cyclopedia of Medicine and Surgery*.)

6. *Scarlet fever:* Period of incubation, from a few hours to seven days. Stage of invasion, twenty-four hours. Character of eruption, a scarlet punctate rash, beginning on neck and chest, then covering face and body; desquamation is scaly or in flakes. The eruption is brighter, is on a red background, punctiform, and is more uniform; the temperature is higher, the pulse quicker; the tongue is of the "strawberry" type, the lymphatics in the neck may be swollen, and there is sore throat; Koplik's spots are absent.

Measles: Period of incubation, ten to twelve days. Stage of invasion, four days. Character of eruption, small dark red papules with crecentic borders, beginning on face and rapidly spreading over entire body; desquamation is branny. The eruption is darker, less uniform, more shotty; the temperature is lower, pulse slower, the tongue is not of the "strawberry" type;

coryza, coughing, and sneezing may be present; Koplik's spots are present.

7. *Diagnosis of cancer of the rectum:* "This is usually easy if the case is examined locally. In the early stages it is impossible to diagnose cancer from piles, prolapse, polypus, or fistula without a rectal examination."

In piles there is no new growth, but merely swollen veins, but it is important to remember that piles often complicate cases of cancer, so that the inside of the bowels should be examined in every case of piles.

In fissure the pain is much more severe, and is almost unbearable on digital examination. A linear ulcer with sentinel pile is evident, and the inside of the bowel is healthy.

In polypus the mass is small and pedunculated, and the mucous membrane healthy.

In fibrous stricture the parts are indolent and there is no new growth. Bleeding on examination is absent or very slight.

In syphilitic disease the gummata are soft, painless, and non-vascular. The ulcers ragged, undermined, and not at all indurated.

In prolapse and intussusception inspection and palpation will make the case clear.

The sigmoidoscope is useful for cases of cancer occurring out of reach of the finger (three to twelve inches from the anus)." (Grove's *Synopsis of Surgery*.)

8. *Laboratory diagnosis of diphtheria:* "In obtaining material from a throat, be sure that an antiseptic gargle has not been used just prior to taking the throat swab. The part of the swab which touched the membrane or suspicious spot should come in contact with the serum slant. This is best accomplished by revolving the swab. An immediate diagnosis is possible in probably 35 per cent. of cases by making a smear from a piece of membrane. In doing this Neisser's stain or the toluidin blue stain are usually considered the most satisfactory. I prefer the Gram stain, however. The diphtheria bacilli found in such smears are not apt to be clubbed and stain more uniformly. If there is any doubt about the nature of an organism in a throat culture, always stain: 1. with Löffler's alkaline methylene blue for two minutes; 2. with Gram's method, being careful not to carry the decolorization too far, and 3. by Neisser's method. With Löffler's you obtain a picture which, after a little experience, is characteristic; at times the polar bodies show as intense blue spots in the lighter blue bacillus. One is liable to confuse cocci lying side by side for diphtheria bacilli with segmental or banded staining. This difficulty is not apparent when Gram's staining is used. This gives us great information, as the diphtheria and the pseudodiphtheria are the only small Gram-positive bacilli usually found in the mouth. The cocci are also well brought out. Neisser's stain gives a picture which, when satisfactory, is almost absolutely characteristic. You have the bright blue dots lying at either end of the light brownish-yellow rods. When first isolated from a throat, the diphtheria bacillus is apt to stain characteristically by Neisser. Later on in subculture, there may be no staining of the polar bodies. Neisser originally recommended five seconds' application, with an intermediate washing, for each of his two solutions. Thirty seconds for each is probably preferable. Some authorities recommend five to thirty minutes. It is well to bear in mind that about 2 per cent. of the people in apparent health carry diphtheria bacilli of the granular or barred type in their throats and of these about one in five will prove virulent for the guinea-pig." (Stitt's *Practical Bacteriology*.)

9. *Five characteristic signs in various syphilitic diseases:* (1) Hutchinson's teeth in congenital syphilis; (2) the chancre in the primary stage of acquired syphilis; (3) the rash in the secondary stage of acquired syphilis; (4) gumma in tertiary stage of acquired syphilis; (5) a positive Wassermann reaction in practically any form of the disease.

10. *In dementia paralytica*, "the diagnosis is based on the history of syphilis, the facial and tongue tremor, irregular and rigid pupils, exaggerated or irregular knee-jerks, the disturbance of speech, weakness of memory, loss of power to work, irritability and change of character, change in the handwriting, and presence of convulsive or apoplectic attacks. Examination of

the cerebrospinal fluid usually shows the presence of monocuclear lymphocytes instead of a normal clear fluid. Cholin is usually found in this fluid.

In *senile dementia*, "the main characteristics are a forgetfulness and mixing of old with new memories, repeating stories and questions; weakness of the power of attention and inability to remember or acquire recent things, and mental fatigue; the lack of interest in new things, apathy, with variability of moods; peevishness, suspiciousness, temper. At times conduct is easily influenced, and at other times the patient is obstinate and perverse. Change of character, episodes of maniacal excitement, and delusions of grandeur or suspicion distinguish the condition from simple dotage." (Dana's *Text-Book of Nervous Diseases and Psychiatry*.)

PATHOLOGY, BACTERIOLOGY, PUBLIC HEALTH, AND HYGIENE.

1. *Repair of fracture*: "The broken ends of the bone are rough and irregular, and the periosteum is torn more or less, but some portion usually remains as a bridge between the fragments. The soft structures in the neighborhood are lacerated, so that the parts are infiltrated with blood clot, which fills up the spaces between the bone ends. As in repair of any other part, the blood clot in a few hours is infiltrated with leucocytes, whose duty it is to absorb the clot. The connective tissue cells in the surrounding parts proliferate, and the bone undergoes rarefying osteitis, so that the place of the blood clot is taken by granulation tissue. The granulation tissue becomes calcified, and the calcified tissue is ultimately replaced by bone. The periosteum plays a large part in the ossification of the new tissue. It becomes stripped up for some distance, hyperemic, and thickened. Granulation tissue is formed from it, and unites with that which has replaced the blood clot. This mass binds the bone together and forms the *provisional and ensheathing callus* which is subsequently ossified by the growth of the periosteal osteoblasts spreading over the mass. The medulla becomes plugged with granulation tissue or *internal callus*, and this, as well as the granulation tissue lying between the fragments of compact bone, becomes ossified, the bone cells of the compact tissue probably proliferating to take part in the repair." (Aids to *Surgery*.)

Faulty union: "Union with marked displacement of the fragments is most common in fractures which have not been properly treated—as, for example, those occurring in sailors at sea; and in cases where the comminution was so great that accurate apposition was rendered impossible. It may also result from imperfect reduction, or because the apparatus employed permitted of secondary displacement. Restlessness on the part of the patient from intractability, delirium tremens, or mania, is the cause of mal-union in some cases." (Thomson and Miles' *Manual of Surgery*.)

2. *Aortic aneurysm*. "In sacular aneurysm of the aorta it is found that the sac most commonly springs from the convexity of the arch, and that intense arteriosclerotic alterations of the aorta surround its mouth. The orifice is round or irregular in outline, and the edge is rolled over into it somewhat, so as to almost overhang its cavity. The cavity itself may reach a very great size, the sac thus formed pushing aside the surrounding organs or embedding itself in them. Mechanical effects produced in this way are of great variety, depending largely upon the point of origin and size of the sac. Pressure on the recurrent laryngeal nerve produces an alteration of the voice from spasm or paralysis of the vocal cord, coughing, dyspnea, etc. Pressure on the trachea flattens it and causes dyspnea—later the aneurysm may rupture into it, after eroding its wall. The lungs yield and collapse before the aneurysm. Pressure on a bronchus narrows it, and behind the obstruction bronchiectasis arises. When the sac reaches the bony structures of the thorax, which do not yield, it hammers its way through them, appearing under the skin through a hole in the ribs or sternum. If it extends backward to the spine, it destroys the centre of the vertebrae even down to the spinal canal, leaving the yielding intervertebral discs standing almost unaltered—in the same way it may break through the ribs in the back and appear under the skin there. Then it is not long before the skin becomes thinned out and bluish, and finally the sac

ruptures, so that death follows at once. Often it ruptures long before it reaches the skin—into the pleura or pericardium, trachea, or esophagus, or even into the superior or inferior vena cava. . . . The sac is not composed of the stretched-out walls of the vessel, for microscopic examination shows that practically all these elements stop sharply at the edge of the orifice. The elastic tissue and the muscle are suddenly interrupted. Endothelium may persist and attempt to line the sac, but it soon fails in this and is lost. Indeed, nothing but connective tissue, and that essentially new formed, goes to make up the sac. It grows largely by new breaks in the wall which seem to be made good by further formation of fibrous tissue. The current of blood eddies about in the cavity, and its pulsation gives the sac its power of breaking down the resistance of the tissues. But the endothelial lining is imperfect, and thrombosis occurs, and if time be allowed, layer after layer of compact thrombus material may be hammered down on the wall of the sac until it is in large part filled up. Occasionally the aneurysm may be completely obliterated in this way. The character of the fibrous wall is such that little upgrowth of organizing granulation tissue into the thrombus appears, and the lower layers become even more compact, until, on a smoothly cut section, they look like onyx. The wall itself becomes hyaline, and it is often impossible to say, in a microscopic section, where the wall ends and the thrombus begins. In the smaller and fresher aneurysmal sacs the wall, wrinkled and irregular, is generally shining, thick, and rather translucent, and quite uncovered with thrombi or covered with only the merest film." (MacCallum's *Text-Book of Pathology*.)

3. "It is also possible that arthritis is of microbic origin, as it is often the sequel to an acute infection, in certain cases its onset is acute, in children there is often wide-spread enlargement of lymphatic glands and of the spleen, and organisms of various kinds have been found in the articular fluid. One view is "that it is due to a settlement of micro-organisms in the affected joints, that they there produce a toxin, and that that toxin, passing into the circulation, is responsible for any nervous symptoms which occur" (Luff). "Another, which has much recent evidence to justify it, is that the joint condition is due to a chronic sapraemia, the result of a local microbic infection." (Wheeler and Jack's *Handbook of Medicine*.)

These local infections are very common in the teeth, giving rise to the so-called focal infections, and pyorrhea alveolaris. The toxins are carried by the blood to the joints, and there the pathological changes occur.

4. The term "*organic heart disease*" includes: Valvular defects (aortic stenosis and regurgitation; mitral stenosis and regurgitation; tricuspid stenosis and regurgitation; and pulmonary stenosis and regurgitation); hypertrophy and dilatation of the myocardium; sinus irregularity; heart block; extrasystoles; bradycardia and tachycardia.

5. The sputum must be recent, free from particles of food or other foreign matter, it must come from the lungs or bronchi and not from the nose or nasopharynx. Disinfectants should not be added to the sputum. To make the microscopic examination: Select a cheesy-looking nodule and smear it on a slide, making the smear as thin as possible. Then cover it with some carbol-fuchsin, and let it steam over a small flame for about two minutes, care being taken that it does not boil. Wash it thoroughly in water and then decolorize by immersing it in a solution of any dilute mineral acid for about a minute. Then make a contrast stain with solution of Loeffler's methylene blue for about a minute; wash it again and examine with oil immersion lens. The tubercle bacilli will appear as thin red rods while all other bacteria will appear blue. The tubercle bacillus is rod shaped, is from 14 to 34 mikrons in length and about one-third to one-half a mikron in breadth, is a strict parasite, is not motile, and has no flagella. It is slightly curved, does not form spores, is not liquefying; is nonchromogenic; is aerobic; it resists acids; it grows well on blood serum; stains well by Ehrlich's, Ziehl-Neelsen's, or Gabbett's method; it is Gram-positive.

With regard to the sending of sputum by mail, the following was issued by the Post Office Department of the U. S.:

"Specimens of diseased tissues may be admitted to the mail for transmission to the United States, State, or municipal laboratories, only when enclosed in mailing packages constructed in accordance with the specifications hereinafter enumerated: Liquid cultures, or cultures of microorganisms in media that are fluid at the ordinary temperature (below 45° C. or 113° F.) are unavailable. Such specimens may be sent in media that remain solid at ordinary temperatures. Upon the outside of every package shall be written or printed the words "Specimen for Bacteriological Examination. This package to be treated as letter mail." No package containing diseased tissue shall be delivered to any representative of any of said laboratories until a permit shall have first been issued by the Postmaster General certifying that said institution has been found to be entitled, in accordance with the requirements of this regulation, to receive such specimens."

The regulation includes not only cultures, but "specimens of diseased tissues." The specifications prescribing the manner of packing, which are minute and complicated, may be obtained from local postmasters.

6. The *colon bacillus* is a rod-shaped microorganism with rounded ends; it is about 2 microns long by 0.5 to 0.7 broad; but sometimes it is oval or nearly spherical; it stains with the ordinary anilin dyes, and is decolorized by Gram's stain; it grows on all the usual culture media; in media containing sugar, it causes fermentation and production of acid and gas; it forms indol.

Isolation of the colon bacillus from mixed cultures is accomplished by plating upon the Endo medium after the addition of bile.

It may be *pathogenic* when some of its poisonous products become absorbed. Such absorption does not occur when the intestinal mucosa is healthy and intact. It may be found in septicemia, peritonitis, appendicitis, cystitis, pyonephrosis and in inflammatory conditions of the liver, gall-bladder, and pancreas.

7. "The routine examination of *spinal fluid* is best made upon the sediment of centrifugalized specimens. The microorganisms with which we deal most frequently in this fluid are the meningococcus, the pneumococcus, the streptococcus, and the tubercle bacillus. If morphological examination reveals bacteria resembling the first three of these in appearance and staining-reaction, surface smears should preferably be made upon plates of serum agar, blood agar, or upon tubes of Loeffler's coagulated blood-serum. Failure to find organisms morphologically does not exclude their presence and careful cultivation should be done in all cases. When organisms are not found by simple morphological examination and the fluid and sediment are scanty, specimens should be stained by the Ziehl-Neelsen method for tubercle bacilli. In such cases it is often of advantage to set away the specimen until a thin thread-like clot of fibrin has formed in the bottom of the tube. In smears of such a clot, tubercle bacilli are found with far greater ease than they are found in centrifugalized specimens. If these examinations are without result, inoculation of guinea-pigs should be resorted to." (Hiss and Zinsser's *Bacteriology*.)

8. *Characteristics of a good drinking water*: (1) It should be clear and limpid. Cloudy and muddy waters should be avoided. (2) It should be colorless. A greenish or yellowish color is usually due to vegetable or animal matter in solution or to organisms. (3) It should be odorless; especially free from sulphuretted hydrogen or putrefactive animal matter. (4) It should not be too cold, but should have a temperature of from 46° F. to 60° F. (5) It should have an agreeable taste; neither flat, salty, nor sweetish. A certain amount of hardness and dissolved gases give a sparkling taste. It should contain from 25 to 50 c.c. of gases per liter, of which 8 to 10 per cent. is carbon dioxide and the rest oxygen and nitrogen. (6) It should be as free as possible from dissolved organic matter, especially of animal origin. (7) It should not contain too great an amount of hardness. A certain quantity of saline matter is necessary, however, to give it a good taste. It should not contain over three or four parts of chlorine in 100,000 parts of water.—(From Bartley's *Chemistry*.)

9. *Industrial diseases due to improper working con-*

ditions: Compressed air illness; bronchitis and nephritis may result from excessive heat and moisture; insolation may occur in stokers and foundrymen; bronchitis may be found in cold storage workers; the eyes may be strained by excessive or inadequate light; miner's phthisis or anthracosis; rhinitis; conjunctivitis; eczema; poisoning of lead, mercury, phosphorus, arsenic, antimony and anilindyes; emphysema; pneumonia.

10. "The object of a medical inspection of schools is not primarily the treatment of diseases, but rather their prevention. One of the principal objects is the early recognition of physical defects such as errors of refraction, imperfect hearing, malformations of the body from abnormal positions, adenoids, enlarged tonsils, and other obstructions of breathing, and sources of inflammation, etc. An important object of the medical inspection of school children is to determine their fitness to enter school and to recognize mental and nervous disorders; also the early recognition of the communicable diseases and measures to prevent their spread; the supervision of vaccination, and disinfection; the teaching of personal hygiene to pupils and teachers, and the sanitation and cleanliness of the school building and its surroundings; the adjustment of the seat and desk, and the medical supervision of the mental and physical work of the child." (Rosenau's *Preventive Medicine and Hygiene*.)

(To be continued.)

Miscellany.

NEW BOOKS AND OLD.

By JOHN RUMRÄH, M.D.

BALTIMORE, MD.

IV—JOHN ARMSTRONG.

A PHYSICIAN of the eighteenth century, far better known as a poet and literary man, John Armstrong led a curious career and has been variously estimated. He was born in 1709 in the parish of Castleton, Roxburghshire, his father was a clergyman and destined his son for the profession of medicine. He studied in Edinburgh and received his degree on February 4, 1732, reading as his thesis "Dissertatio de Tabæ purulenta." This inaugural dissertation is the first volume of William Smellie's "Thesaurus Medicus." It is dedicated to Hans Sloane.

Turning his way to London he took to the practice of physic and poetry. He was a prolific writer; medical papers and books, poems and plays flowing from his pen in rapid succession. His first venture was an article "On Penetrating Topic Medicines" in 1734, followed in the same year by "Alcaescent Disposition of Animal Fluids." The following year he turned out a satire entitled "Essay for Abridging the Study of Physic." The succeeding year he published anonymously a very poor poem entitled "Economy of Love." After a silence of eight years the "Art of Preserving Health," a poem in four books, appeared. This had great vogue and was reprinted many times.

When Dr. W. A. Alcott reprinted the poem in Boston in 1838 he stated in the preface that "the two passages which I have omitted related exclusively to the occasional use of wine, which the doctor, with strange but very common inconsistency, seems inclined to permit." This is extremely interesting as it shows the inevitable tendency to censor a practice so dear to the heart of the reformer. Imagine the editions of the Bible, Omar,

Shakespeare, *et al.* as the Anti-saloon League would doubtless have them reprinted. Think not that this is a jest. What has happened can easily happen again.

Hugh Downman, himself the author of a pediatric poem, in it pays the following tribute to Armstrong:

... nor blind to worth,
 The still upon this wave worn shore it stood
 Of troublous life, by enemies blasts assail'd
 Be thou ungreeted, Armstrong, in my verse,
 Thou parent of the prophylactic lay.

Armstrong's description of the sweating sickness which ends the third book of the poem is one of the best parts of it.

... A monster never known before,
 Reared from Cocytus its portentous head:
 This rapid Fury not, like other pests,
 Pursued a gradual course, but in a day
 Rushed as a storm o'er half the astonished isle,
 And strewn with sudden carcasses the land.

First through the shoulders, or whatever part
 Was seized the first, a fervid vapor sprang.
 With rash combustion thence, the quivering spark
 Shot to the heart, and kindled all within;
 And soon the surface caught the spreading fires.
 Through all the yielding pores the melted blood
 Gushed out in smoky sweats; but nought assuaged

The torrid heat within, nor aught relieved
 The stomach's anguish. With incessant toil
 Desperate of ease, impatient of their pain,
 They tossed from side to side. In vain the stream
 Ran full and clear—they burnt and thrashed still.
 The restless arteries with rapid blood
 Beat strong and frequent. Thick and pantingly
 The breath was fetched, and with huge laborings heard.
 At last a heavy pain oppressed the head—
 A wild delirium came; their weeping friends
 Were strangers now, and this no home of theirs.
 Harassed with toil on toil, the sinking powers
 Lay prostrate and o'erthrown; a ponderous sleep
 Wrapt all the senses up. They slept and died.

In 1746 we read of his serving as physician to the Hospital for Lame, Maimed and Sick Soldiers in London. Practice, however, did not keep him from his literary activities; 1751 saw the appearance of "Benevolence, an Epistle"; two years later, "Taste, an Epistle to a Young Critic." Next he tried his hand at tragedy, "The Forced Marriage," which was written in 1754, but not printed until 1770. In 1758 he published, under the pseudonym of Launcelot Temple, "Sketches or Essays on Various Subjects." In 1760 he secured the post of physician to the army in Germany. "Day, a Poetical Epistle," resulted in an acrimonious controversy with Wilkes. Returning from the army he was retired on half pay. In 1770 he published the volumes of miscellanies. At this time he made a tour of Italy and France, stopping at Leghorn to visit the dying Smollet. His travels are described in "A Short Ramble Through France and Italy." In 1773 he printed his "Medical Essays."

He died as the result of a fall on September 7, 1779. He left three thousand pounds, quite a sum in those days, so that he must have lived rather parsimoniously. Armstrong was a man about whom there are many opinions. There is a mezzotint portrait from a painting by Sir Joshua Reynolds inscribed:

"John Armstrong, The suffrage of the wise,
 the praise that's worth competition is attained
 by sense alone and dignity of mind."

The Rev. Henry Francis Cary includes a short account of Armstrong in his "Lives of the English Poets." He states that early in his career he published "a licentious poem, which I have not seen, and the title of which I do not think it necessary to record." He also states "His Art of Preserving Health" is the only production by which he is likely to be remembered.

The industrious John Aiken wrote a critical essay on the poem that has been reprinted in some of the editions.

Dr. Cuming of Dorchester said: "He always appeared to me (and I was confirmed in this opinion by that of his most intimate friends) a man of learning and genius, of considerable ability in his profession, of great benevolence and goodness of heart, fond of associating with men of parts and genius, but indolent and inactive, and therefore totally unqualified to employ the means that usually lead to medical employment or to elbow his way through a crowd of competitors."

In 1773, Armstrong wrote concerning himself that "he could neither tell a heap of lies in his own praise wherever he went; nor intrigue with nurses; nor associate much less assimilate with the various knots of pert, insipid, lively, stupid, well-bred, impertinent, good humored, malicious, obliging, deceitful, washy drivelling gossips; nor enter into juntos with people not to his liking."

In Thomson's "Castle of Indolence" there are some lines supposed to refer to Armstrong.

With him was sometimes join'd, in silent walk
 (Profoundly silent, for they never spoke),
 One shyer still, who quite detested talk:
 Oft, stung by spleen, at once away he broke
 To groves of pine and broad o'er shadowing oak;
 There, inly thrilled, he wandered all alone
 And on himself his pensive fury wroke,
 Nor ever utter'd word, save when shone
 The glittering star of Eve—"Thank Heaven, the day is done."

Churchill's posthumous satire "A Journey," in 1764, took a fling at him as follows:

Let them with Armstrong, taking leave of sense,
 Read musty lectures on Benevolence,
 Or con the pages of his gaping Day,
 Where all his former fame was thrown away,
 Where all but barren labour was forgot
 And the vain stiffness of a lettered Scot.

All the above apropos of the two copies of Armstrong's poem, "The Art of Preserving Health," which the Medical and Chirurgical Faculty recently acquired at small expense. If your library does not boast a copy of this poem, now is a good time to pick one up in England for a nominal sum.

11 EAST CHASE STREET.

Rights of the Pharmacist Against the Physician.—Perreau reports on the ethics of a pharmacist towards a physician's prescription. One of two contingencies may arise, the first of course when the prescription itself is in violation of some legal restriction, and the second, when in the judgment of the pharmacist the prescription might injure the patient. In refusing he should give his reasons and be moderate in his language. If the prescription is merely worthless for any reason he may communicate with the prescriber before refusing to fill and must not inform the patient of the transaction. He can say nothing which reflects discredit upon the physician. In damage suits by physicians against pharmacists the plaintiff must show intent to injure him, and wilful publicity on the part of the defendant. The plaintiff must also be shown to have committed a definite statutory offence.—*Journal de médecine et de chirurgie pratiques.*

SPECIALIZATION IN THE MEDICAL AND SURGICAL TREATMENT OF ULCERS OF THE STOMACH AND DUODENUM.

By ANGELO L. SORESI, M.D.,

NEW YORK.

VISITING SURGEON, GREENPOINT HOSPITAL.

THE rational treatment of ulcers of the stomach and duodenum must obviously be based on an exact diagnosis. No symptom is pathognomonic of the presence of ulcer in the stomach and duodenum; the diagnosis must be made on the interpretation of facts collected by the history, physical examination, gastric analysis, and roentgen-ray investigation. *The physical examination and the history have not lost any importance since the other means have come into use, and we believe them to be still the most important elements if properly collected.* The physical examination is important, mostly because it might reveal lesions of other organs beside the digestive ones. The gastric analysis and roentgen-ray investigations are a great help, but are often misleading. Some of the mistakes caused directly by the roentgen-ray are well illustrated in the following cases:

CASE I.—A nun, aged 64 years, suffered for years from stomach trouble. The history and gastric analysis pointed to the presence of chronic ulcer of the stomach, probably cancerous; no mass could be palpated. The roentgen-ray showed a filling defect in the region of the pylorus. (Fig. 1.) All investigations and the operation were performed at St. Catherine's Hospital in Brooklyn. At operation the pylorus was seen to be absolutely normal; an ulcer that proved to be carcinomatous, and of a size somewhat larger than a silver dollar, was found in correspondence to the small curvature, close to the cardia.

CASE II.—A woman, aged 23, six months previously operated on for chronic appendicitis, had symptoms unimproved, and various physicians made a diagnosis of ulcer of the duodenum. The Roentgen rays showed constant deformity of the duodenal cap. (Fig. 2.) I was called to operate on this patient as a clear case of ulcer, in order to demonstrate my technique for gastroenterostomy to local surgeons in Scranton, Pa., after having read a paper before their county medical society. On operation, the stomach, duodenum, biliary tracts, in fact all the abdominal organs, were absolutely normal.

CASE III.—A woman, aged 29, whose past history gave nothing worthy of notice, except that her appendix was removed when she was eighteen years of age, about two years ago began to complain of stomach troubles and was under the care of several physicians. A gastroenterologist made a diagnosis of duodenal ulcer, treated her for several months, and the patient was apparently cured and remained well for about a year. Her troubles recurred and the patient went back to the gastroenterologist, who stated that the ulcer had recurred and started the same treatment again which

had been successfully followed previously. The patient's condition did not improve very satisfactorily, until she finally began to vomit. Consultations with other specialists were held and the gastroenterologist advised surgical intervention, his diagnosis being always duodenal ulcer with pylorospasm. The patient came to me with the history referred, asking to be operated upon. From the complete investigations which I carry on in similar cases, I felt that I had to deal with a neurotic subject, and notwithstanding the constant deformity of the duodenal cap, as shown in the roentgenograms (Fig. 3) I thought operation was not advisable, because I did and do believe that all the patient's troubles were caused by reflexes due to the early removal of the appendix. However, the patient and relatives were so convinced that only an operation could effect a cure that I operated on the young woman only a few weeks ago in a private sanatorium. No lesion of any kind could be detected in any abdominal organ, except adhesions between the cecum, the ileum, and the omentum.

CASE IV.—J. L., female, aged 32, gave history of long suffering from internal troubles. She was referred by her physicians to one of the most competent gastroenterologists in town, who: after an unsuccessful treatment for duodenal ulcer, advised surgical intervention. The x-ray report (Figs. 4 and 5) by a competent radiologist stated: "The consideration of a probable early ulceration in the first portion of the duodenum should be entertained. The condition of marked periceal adhesions should not be overlooked." I was called on to operate on Mrs. J. L. Because the case had been studied by competent men and the lady, who appeared to be very intelligent and self-composed, insisted on early operation, and would not have allowed further investigations, being convinced that she was suffering from an ulcer of the stomach that could only be cured by operation, the operation seemed really indicated, the diagnosis of ulcer of the duodenum was accepted, and the lady was operated on. At the operation nothing abnormal could be found; on the suggestion of the family physician that the appendix might show some pathology, the appendix was removed. It was absolutely normal. As the sufferings complained of by the patient seemed to be real I made inquiries about her family life and found that she and her husband, although living together, were so estranged that no sexual rapports had existed between them for a long time, and the patient suffered therefrom.

These cases prove that mere gastroanalysis and roentgen-ray investigations do actually mislead. In the first case the gastric analysis and the history gave correct indications for the diagnosis; the roentgen-ray instead gave wrong indications as to the location of the ulcer and did not reveal such a large ulcer as the one that was found at the operation. In the second case the gastric analysis and roentgen rays completely misled the physicians, and finally in the third case a competent gastroenterologist had once cured an ulcer of the duodenum that had never existed, and recommended surgical intervention for a recurrence and aggravation of the same phantom ulcer of the duodenum. The gastric analysis, the roentgen rays, and the treatment—ap-

parently successful—had completely misled the physicians who had studied the case.

Case IV was extremely interesting because it proved many of the contentions made in this paper and emphasized, not only the fact that x-ray, lab-

FIG. 1.—Case I. X-ray pictures show a filling defect in the region of the pylorus; the lesion, however, was close to cardias.

oratory analysis, and physical examination may lead to a wrong diagnosis, but because it showed the importance of properly taking the history, *that must give the greatest consideration to the psychic factor in analyzing complaints referred to the digestive organs.* The importance of the psychic factor is confirmed in the case by the fact that Mrs. J. L. is better now because since the operation there has been a better understanding between her and her husband.

In attempting a diagnosis of ulcer of the duodenum and stomach, the history, the physical examination, any method of gastroanalysis, and roentgen rays can mislead the physician, if he does not take *the psychic factor into consideration.* All psychic troubles do influence the function of the stomach, and when the patient has been treated for some time on account of stomach troubles that were only reflex troubles—as is often the case—he feels convinced and often convinces the physician, that his or her troubles really depend on the stomach, so that the history, if not wisely taken, and the physical examination may lead to false conclusions. The gastric analysis and roentgen-ray investigations are often carried on as if the stomach were a mere bag, where certain chemical and contour changes take place. It is sufficient to mention that the fear of the stomach tube, of the investigations that might reveal serious conditions, the test meal or the barium meal itself, will influence the secretions, the motility, and all the complex functions of the stomach. To understand that unless the psychic factor is taken into serious consideration, sad and frequent mistakes will be made, and that mere reports, even from very competent men, should not be sufficient to allow any physician or surgeon to make a diagnosis of ulcer of the stomach or duodenum in all

cases; these reports should not even be suggestive, because the word "suggestive" in these cases means "misleading." We like to emphasize the fact that the x-rays would greatly facilitate the diagnosis of ulcer of the stomach and duodenum, if instead of relying solely on what is shown on the plates obtained following the routine technique, *the competent radiologist would examine carefully each patient with the fluoroscope and draw his conclusions on what he observes directly on the screen.*

Ulcer of the stomach and duodenum is diagnosed more frequently by the patient himself, less frequently by the general practitioner, still less frequently by the good internist or the gastroenterologist, again less frequently by the experienced surgeon, and finally less frequently yet by the competent, thorough gastroenterologist, such as we understand he should be.

The treatment of ulcer of the stomach and duodenum must be based on a complete understanding of the physiology of the digestive organs, and in altering their normal physiological rapports and functions as little as possible, and any treatment either medical or surgical that will preserve them will be more successful than when these rapports and functions are greatly altered or destroyed.

Patients suffering from ulcer of the stomach and duodenum are treated by general practitioners, internists, gastroenterologists, and surgeons. The most successful is the general practitioner; then in order come the internist, the gastroenterologists, and lastly the surgeon. It is easy to understand the main reason why the surgeon comes last; he is the

FIG. 2.—Case II. Picture shows deformity of the cap, but no lesion was present.

only one who actually sees and feels the ulcer, and is the one who has to tackle the problem of curing an ulcer that really does exist; *his task is more difficult than the treatment of a phantom ulcer, very cleverly diagnosed by the internist.*

It is common to divide the treatment of ulcers of the stomach and duodenum into medical and surgical treatments. Does either treatment remove the real cause? I do believe that no internist, surgeon, or the most enthusiastic local focalist will think that

Fig. 3.—Case III. Shows the same condition as Case II.
Fig. 2.

he does remove the *cause prima*, because the real pathogenesis of ulcer of the stomach and duodenum has yet to be demonstrated. A rational treatment must be based on a complete understanding of the pathology and of the value of each therapeutic means, and obviously this knowledge must be concentrated in the one man who intends to undertake the rational treatment of ulcers of the stomach and of the duodenum. Does any such man exist to-day? We have many gastroenterologists who are very competent diagnosticians, and who are supposed to be what is commonly called stomach specialists. But, may I ask, what kind of specialist is the gastroenterologist who refers his most difficult and stubborn cases to the surgeon? Don't you think it sounds rather awkward to be called a specialist along a certain line, which means that the specialist should have the ability to deal thoroughly with the most difficult problems that concern his specialty, when this qualification is applied to the gastroenterologist? A gastroenterologist is consulted by a patient who is studied carefully by him. This patient has an ulcer of the stomach or of the duodenum. The gastroenterologist starts an internal treatment which lasts some time. The patient is not improved or his condition grows worse. What does the gastroenterologist, the specialist, do? He refers the patient to the surgeon. His talk to the patient is not literally, but certainly sounds like this: "I am a stomach specialist, I am one of the most competent, if not the most competent, gastroenterologists, but the condition of your ulcer is such

that I, although a specialist in this branch, cannot do anything personally, but advise you to go to a mere surgeon, who does not know as much as I do about stomach troubles, but, anyhow, will cure you."

I would like to ask gastroenterologists a very plain question: Do you believe that in a certain number of cases of ulcer of the stomach or duodenum surgery of some kind is necessary to effect a cure, or at least an improvement? Either you believe that in certain cases surgery is necessary and then learn how to do it yourselves, or you do not believe in surgery and then do not send any of your patients to the surgeon. I say: do surgery yourselves if you believe in surgery, because when you send your patients to the surgeons you do not know what is being done to them; because the patient acquires the false idea that, after all, surgery is better than medicine; because he thinks he is cured after any kind of surgical operation, no matter what the procedure may be. No surgical operation constitutes the whole treatment in cases of ulcer of the stomach or of the duodenum, no matter what kind of operation or series of operations have been performed, the real *causa prima* is not removed, since in the greater majority of cases this *causa prima* is not known, and mainly because any operation will alter the physiological function of the stomach and intestines. These facts have to be considered, because they are of the utmost importance. The surgeon used to consider cured the patients who recovered from the operation; now the follow-up system has shown that many patients are not cured at all, and some are even much worse than

Fig. 4.—Case IV. The x-ray picture shows an apparent duodenal ulcer that did not exist.

before the operation. We may say that the surgeon is not competent to understand the complete rational treatment of ulcers of the stomach and duodenum; indeed, practically in all cases he refers the patient back to the internist or the gastroenterol-

ogist. But what do the internist and the gastroenterologist know of the new physiology created by the operative procedures? Yes, they admit perhaps that medical treatment must follow each and every surgical intervention, but what kind of medical treatment? Naturally this treatment cannot be the same as that which was used before the operation, because the anatomical relations, shape, size, and function of the digestive organs have changed, and, therefore, the treatment must conform itself to the new conditions created by the operation. Who is competent to judge of all these elements? Obviously not the surgeon, who is not interested in the medical treatment, not the gastroenterologist, who cannot know what changes have taken place. It is evident, therefore, that the real gastroenterologist who wants to undertake the treatment of cases suffering from ulcer of the stomach and duodenum must be

FIG. 5.—Case IV. Showing apparent adhesion in the ceval region that did not exist.

the same man who makes the diagnosis, applies the medical or surgical treatment required in each case, according to the patient's age, sex, and physical, mental, and social condition; the location and duration of the ulcer, and certainty or uncertainty of diagnosis. And when this complete gastroenterologist has been developed, we shall not hear any useless discussion on the antagonistic value of internal and surgical treatment, and have the gastroenterologist point out the mistakes made by the surgeon, and *vice versa*, because valuable time will not be wasted by the real gastroenterologist with stomach tubes and buckets, when the patient has a chronic indurated ulcer, and we shall not see young boys and, girls especially, operated on for duodenal ulcers due to anemic conditions, which can be cured in the greatest majority of cases by proper internal treatment better than by any surgical procedure.

Actual personal experience at the operative table will teach the gastroenterologist many valuable lessons; and we believe that the gastroenterologist of the future must be a competent diagnostician who can judge of the value of each diagnostic means, such as history, physical examination, gastric analysis, and roentgen rays and know how to apply it to each individual case; must have had actual personal experience in applying the rational and complete medical and surgical treatment appropriate to each case; must be able to improve his diagnostic ability by actual visualization of conditions at operation; must follow his cases, and so profit by his own mistakes, which are the only ones that leave a deep impression and teach a valuable lesson.

220 WEST FIFTY-NINTH STREET.

A TECHNIC OF INTRAMUSCULAR (EPIDERMAL) INJECTION

BY JOHN H. STOKES, M.D.,

ROCHESTER, MINN.

CHIEF OF SECTION ON DERMATOLOGY AND SYPHILIGOLOGY, MAYO CLINIC.

SO-CALLED intramuscular injection is a procedure technical acquaintance with which is generally taken for granted in therapeutic instructions so that a rehearsal of the steps of the procedure seems correspondingly uncalled for. Observations extending over several years have led me to suspect, however, that this method of administering medication in general, and mercurial preparations in particular, involves certain principles and a degree of manual dexterity for its accomplishment *secundum artem* with which physicians are often unfamiliar. A folder recently issued by a pharmaceutical concern, purporting to describe a satisfactory technic for the intramuscular injection of one of its preparations, seems, at least so far as its illustrations go, to violate the first principles of intramuscular technic. For these reasons the following description of a mode of procedure which has proved serviceable in about 40,000 injections is offered.

My experience with the injection of large quantities of solutions (100 c.c. or more) into the buttocks directed my attention to a phenomenon which suggested that the contents of the so-called intramuscular injection when properly introduced are deposited not within the body of the gluteus maximus or between its fasciculi nor yet within the subcutaneous fat, but in the areolar tissue on the upper surface of the fascia forming the extension of the fascia lata covering the gluteus maximus. A large quantity of fluid when thus injected, instead of forming a tense induration in the body of the muscle or spreading laterally onto the hip and thigh or appearing at the sacral margin, presents promptly at the lower border of the buttock in the gluteal sulcus. The markedly better absorption thus obtained and the freedom from local irritation even on the injection of a highly irritating drug were demonstrated by the work of Wechselmann and Eicke* who advocated this technic for the comparatively painless and uncomplicated administration of arsphenamine intramuscularly. A similar principle may be employed

*Wechselmann and Eicke: Zur Technik und Wirkung subkutaner Neosalvarseninjektionen. *Münch. med. Wochenschr.*, 1914, lxi, 535-538.

in the administration of the mercurial preparations into the tissue of the buttock with equally satisfactory results. The technical detail necessary to achieve this end, and the avoidance of other familiar complications of intramuscular injection such as

FIG. 1.—Prone position for intramuscular injection, showing arms hanging over the sides of the table to promote relaxation.

deep and superficial infiltrations, embolism, necrosis, and abscess formation, may be briefly described as follows:

1. *The Position of the Patient.*—Injections into the buttock are given to best advantage with the patient lying prone on a table. Other positions induce tenseness of the tissues, which favors leakage of the injected substance along the needle track, makes a careful estimation of the depth of tissue and the placing of the needle difficult, and also makes it difficult to avoid mechanical awkwardness in carrying out the procedure.

FIG. 2.—a, "Toed in" to show the relaxation of the buttock. b, "Toed out" with the dimpling of the buttock indicative of a tense musculature.

Relaxation after the patient assumes the prone position should be complete. Attention to certain details assists in securing a satisfactory cooperation on this point. The patient should drop his arms

over the side of the table (Fig. 1). His legs should be placed in a position of moderate internal rotation "toed in" (Fig. 2a). The difference in the appearance of the buttock when the patient attempts to keep the heels together is well shown in Figure 2. Dimpling of the lower outer quadrant of the buttock as shown in (b) disturbs the anatomical relations, is a sign of incomplete relaxation, and is the position ordinarily assumed by every patient who fears the introduction of the needle.

2. *Instruments.*—The 2 c.c. glass Luer syringe and three lengths of needles, one for very thin or flabby buttocks; one for medium, and one for fat buttocks are necessary. The aspiration technic described herewith for detecting the presence of a needle in a vein makes possible the use of a smaller gauge needle than that required when the venous pressure alone is depended on to yield a flow of blood from a misplaced needle. My preference is for 22 gauge needles 1.5 inches, 2 inches, and 2.5 inches from the tip of the hub to the point (Fig. 3).

3. *Point of Injection.*—Injections into the buttock should, in general, be given into the upper outer quadrant near its inner angle, approximately at the point indicated by a dot in Figure 4. If the injection is given into the upper part of the outer quad-

FIG. 3.—All glass Luer syringe with the various sizes of needles used for intramuscular injection.

rant or into the inner quadrant near the sacrum, even a short needle is likely to strike bone, or the injection of the irritant substance above the periosteum or about the roots of the sacral plexus will give rise to induration and pain, and may, as Neisser points out, induce an obstinate sciatica. Injections given into either of the lower quadrants are subject to pressure on sitting, and are correspondingly painful. If administered near the great sciatic nerve a neuritis may result. Such injections, moreover, cannot be deposited on the fascia with the exactitude possible in the upper outer quadrant, and for this reason are likely to give rise either to superficial nodule formation, abscesses, or deep firm indurations.

4. *Technic of Injection.*—The syringe and needle may be sterilized with alcohol. The alcohol should be thoroughly expelled from the syringe and the needle wiped with sterile cotton moistened with alcohol. The emulsion is then aspirated into the syringe through the needle which has been previously attached, and the needle is again wiped. The syringe is grasped in the right hand (Fig. 5). The left hand is placed flat on the buttock and with moderate pressure is drawn firmly downward toward the

patient's heel, thus flattening and fixing the tissues (Fig. 6). The syringe is introduced to its full length by a quick stroke at an angle of approximately twenty degrees from the vertical in a sagittal plane, with a slight inclination inward (Fig. 7).

FIG. 4.—Outline of the buttock and pelvic bones illustrating (black dot) the point in the upper outer quadrant, about which injections may be made to the best advantage.

The removal of the left hand slightly increases the slant of the syringe. During the process of introducing the needle the piston must be controlled by the pressure of the index finger against it above the barrel, to prevent the leaking of a solution or thin emulsion.

5. *Testing for the Presence of the Needle in a Blood Vessel.*—As soon as the needle is introduced the syringe is steadied with the left hand while an attempt is made to aspirate by pulling upward on the piston with the right hand (Fig. 8). This at-

FIG. 5.—Right hand holding the syringe.

tempt should be continued for at least ten seconds. This in my experience is an entirely safe and much more trustworthy method of detecting puncture of a deep vein or capillary than is the mere detaching of the syringe or the introduction of an empty

needle in the expectation that the pressure of the blood in a capillary vessel will cause a backflow of emulsion or of blood, as the case may be. I have never seen an accident of any type occur if the aspiration step in the technic was rigidly adhered to. As soon as it appears that nothing can be aspirated from the deep tissue about the needle point, the contents of the syringe may be injected (Fig. 9), the right hand maintaining the proper angle of the needle.

It is not necessary in this technic to use a sign, such as Wechselmann's torsion sign, for demonstrating that the needle point is near or on the fascia. The site of the injection, the length of the needle when properly adapted to the type of buttock, the fixation of the tissue with the left hand, and the position of the syringe when introduced soon become matters of habit and seem to place the injected material in such a way that induration is a very unusual occurrence. The flow of injected material into

FIG. 6.—Left hand drawing down the buttock.

the tissue should be free and the needle point should not "feel" as if stuck in a board. A little experience soon enables one to control the technic by recognizing the deep, painful lemon or orange sized induration that has followed on too deep injection (intramuscular) and the hazel-nut to hickory-nut sized nodule in the skin or panniculus secondary to too superficial injection or to leakage along the needle track.

Deposition of injected material along the needle track is avoided; first, by securing complete relaxation; second, by using a small caliber needle; third, by completely emptying the syringe before withdrawal; fourth, by a rapid withdrawal; fifth, by quickly pushing the tissues which have been drawn downward by the left hand back to their normal position like a sliding valve the moment the needle is withdrawn; and sixth, by light massage with a cotton pledget over the site of puncture which results in a rapid flattening out of the injection mass in the

areolar tissues over the fascia (Fig. 10). In buttocks which have been rendered fibrous by repeated courses of intramuscular injections, leakage cannot be prevented, and the intramuscular injections must ultimately be abandoned.

Attention to several additional details materially contributes to a uniformly satisfactory technic. It goes without saying that the buttocks should be used in alternation for injection. Needle points should be of a rather long bevel and exceedingly sharp. The use of a needle with a turned point is very painful. In wiping the needle a turned point can be detected by a grating sound and feel as it passes over the cotton, often when it is scarcely visible. The operator may unconsciously turn the point of his needle by touching it against the bottom of his bottle of emulsion or solution when filling the syringe. For this reason every movement of the needle should be carefully controlled and it should never be brought into contact with hard substances. A needle which

If a Needle Breaks.—First, do not exclaim or discuss the situation with the patient or the nurse; second, keep the left hand in position until an attempt can be made to recover the needle. The usual point of fracture is at the juncture of the hub and shaft

FIG. 7.—Introduction of the syringe.

has been allowed to become rusty, corroded, or pitted will also bring a protest from the patient.

The breaking of a needle is one of the most unpleasant complications of intramuscular injection and may be due first, to an incorrectly placed puncture which causes the needle to strike on bone, fracturing it at some point along the shaft; second, to a sudden movement on the part of the patient, especially if the point is caught in the fascia or lies in the muscle, and third, to weakening of the needle by internal or external corrosion. The first cause seldom operates except as a result of gross misjudgment. The second can usually be avoided by an effort to secure the cooperation of the patient and by guarding against sudden movement in those in whom cooperation cannot be expected (children for example). The third cause can be controlled by frequent inspection of needles with a forcible attempt to bend the shaft on the hub. If a steel needle is used for corrosive solutions, its life will be short and inspection must be frequent and critical.

FIG. 8.—Aspiration to test for the presence of the needle in a vein.

and with an assistant at hand the fragment just beneath the skin may sometimes be recovered by a small incision and with the aid of a hemostat if the

FIG. 9.—Injection; the emulsion or solution should flow in freely and not have to be forced.

operator keeps his presence of mind. On the other hand, the moment the left hand is released from the buttock the needle is lost and can usually only be identified by the roentgen ray and removed through an extensive surgical incision. Such situations are

so embarrassing that the finest types of steel and tempered gold needles should be used for intramuscular work.

In the use of insoluble suspensions for intramuscular injection a word of caution as to the preparation of the suspension is important. Concentrated suspensions requiring small amounts for each injection are often less painful than thin suspensions. An insoluble preparation made up in a fluid base, settles rapidly and the collected powder can only be returned to suspension by from five to twenty minutes persistent vigorous shaking, and kept in suspension by shaking after each injection. The suspension may appear entirely homogeneous when a considerable portion of the solid material still adheres to the bottom of the bottle. A satisfactory test of complete suspension consists of shaking until none of the suspension can be recognized in the groove at the juncture of the sides and bottom of the bottle when the bottle is inverted.

FIG. 10.—On release of the left hand the tissues of the buttock return to their normal position, producing a valvular action. The emulsion is spread out in the epifascial tissue and leakage prevented by massage with a cotton pledget.

6. *Treatment of Complications.*—If blood is obtained on aspiration after the introduction of the syringe, even in the minutest amount, the syringe should be withdrawn and the procedure repeated 1 cm. or more from the site of the unsuccessful attempt. To continue the injection in the face of a return of blood or even a tinged suspension may be attended by fatal consequences from embolism.

Superficial indurations or nodules may be treated by painting them once or twice a week with iodine and requesting the patient to pinch and massage them between the thumb and forefinger. Deep indurations attended with pain from injection below the fascia are much relieved by prolonged hot applications and massage. Indurations seem to occur with special frequency in certain subjects, especially the obese, and are sometimes unavoidable even with the best technic. Each node represents a certain amount of encapsulated mercury which may be

abruptly released for absorption by trifling trauma such as that of sitting down more heavily than usually. The sudden onset of salivation in patients who have not had intramuscular injections of insoluble mercurial salts for a considerable period may be to some extent a result of technical errors which have interfered with absorption. There can be no object in continuing a method of administration in which persistent nodule formation, even with a careful technic, shows that the drug does not absorb.

Pain referred down the leg has always in my experience been evidence of the technical error of injecting too deep or too near the sacral plexus and the great sciatic nerve.

Pulmonary embolism following the use of insoluble salts, such as mercury salicylate, calomel, and gray oil, probably cannot be absolutely avoided but should be an excessively rare occurrence. The symptoms of pulmonary embolism may vary from a slight and transient cough after the patient rises from the table to evidences of extensive pulmonary infraction with severe and persistent cough, rise of temperature, pleural irritation, and occasional pneumonic complications. Pulmonary embolism may occasionally supervene some hours after an injection made in accordance with the strictest technical exactness. Cerebral embolism is exceedingly rare.

Abscess formation I have seen only twice in 40,000 injections. The abscess is usually sterile and resolves promptly on evacuation. A certain percentage of deep indurations doubtless undergo central softening, but under rest and hot dressings the process subsides.

BACKACHE.

A CONSIDERATION OF LOW BACK PAIN OF A MILD TYPE.*

BY SIGMUND EPSTEIN M.D.,

NEW YORK.

ORTHOPEDIC CHIEF, MOUNT SINAI DISPENSARY AND BRONX HOSPITAL.

FORTY years ago the plaster-of-paris jacket treatment of spinal diseases and deformities had been firmly established by the late Lewis A. Sayre. The jacket has since received much criticism; it remains to-day, however, the sheet-anchor for spinal injuries and inflammations. Still there exists in many minds the fear that patients and their doctors express, "that they are heavy, and they interfere with breathing." This can be answered in a satisfactory manner. We have learned to avoid many mistakes of commission and omission in their application, as well as in the selection of suitable cases for their use. The plaster room is one of the busiest spots in any orthopedic dispensary or clinic. We have learned to instruct parents or attendants in the art of keeping the skin clean and free from accidentally dropped crumbs, coins, keys, etc.; the use of suitable felt for padding, over spinous processes or bony points is a small detail carefully watched over by trained attendants, so that we are no longer surprised to see instances, where the appliance has been worn for one or two years, with entire comfort. With experience has come better judgment in the removal of jackets at the proper time, to be replaced by light braces. The use of such adjuncts as the jury-mast and the shoulder straps, and the in-

*Paper read before the New York Physicians' Association, November 23, 1920.

vention of ingenious apparatus to facilitate the process of applying them, are all evidences of progress in a fertile field. We make them thinner and stronger, and we ventilate them better than we did a decade ago.

FIG. 1.—Spöndylitis deformans.

All this is intended as a preface for a discussion of some comparatively mild cases of pain in the lower back in adults, and in whom plaster-of-paris jackets are measures of prime importance in the relief of pain.

Mild cases of traumatic spondylitis are often seen, the result of blows on the back, or falls, more or less severe. A few days' rest in bed is followed by a period comparatively free from pain. A few months later, in the same locality, the patient experiences a sudden shock or darting pain in the lumbar or dorsal region. This recurrence is dated definitely to a time when he was bending forward at his work or lifting some heavy weight. Shortly after this a small gibbus appears, looking like that of Pott's disease. Here we have a post-traumatic softening of part of a vertebra, not by the tubercle bacillus, as the cause of the disability. If a demonstrable injury to a vertebral body is present, a plaster jacket, with or without extension and counter-extension, is an excellent method of treatment. A transverse process fracture, or an isolated spinous process fracture can be treated by strapping and a period of rest.

There is a class of infectious arthritides of the spine which I would have you consider. Their duration is short, they are common in the lumbar region, and they are often accompanied by a peculiar lateral deformity, or sidewise list of the trunk. They might be classed as chronic lumbago, but are most likely to be called "sacroiliac," because the word sounds good. These patients suffer from sharp pain in the back, in the buttocks, and down one or the other sciatic nerve. Medication does them no good, and perineural or epidural injections are vain procedures, as the patients will tell you. Some of the x-ray plates will bring out the reason why plaster jackets relieve and cure them very promptly. From the iliac crests downward these patients look symmetrical, but one side of the pelvis appears to be much larger than the other, the fact being that the

trunk has shifted laterally upon the last lumbar vertebra. In some we see destruction of part of the body of this fifth lumbar. In others the affection consists of an atrophic process in the intervertebral disc, with or without adhesions and ankylosis. Without support these patients suffer from a series of recurrent attacks of backache, due to an infectious arthritis.

Mention must be made of another type of spondylitis that is diffuse, progressive, polyarticular, and eventuates in the bow-back or poker-back deformity. In the early stage of this crippling affection, a jacket is indispensable to straighten out the distressing bend in the spine. Some of the cases are hereditary, some of them are traceable to gonorrheal urethritis, and a large percentage of older patients present an osteoarthritis, essentially senile in nature.

Two French authors, Lance and Jaubert, have described a number of interesting cases of a familiar, rigid form in soldiers. Six out of their eighteen cases suffered from tuberculosis of the lungs, or from testicular tuberculosis, while one had been sent to their Alpine Hospital for grave anemia. I have seen a number of cases that could be definitely traced to the toxins of infection from softened tuberculous lesions.

When trauma occurs, or is ascribed as the direct cause, it can be shown by an x-ray plate; the loosening of a little spicule, or adhesion at the margins of one of these vertebrae, can be demonstrated. This differentiation is often a matter for wise judgment in courts of compensation.

Backaches are said to be occasionally due to impingement of the lateral processes of fifth lumbar upon the adjacent iliac bones; without stereoscopic plates, carefully studied, these shadows overlap and

FIG. 2.—Senile spondylitis.

lead some surgeons to operate. I believe that the postoperative rest that must follow after such an ordeal cures the patient; it is to be hoped that these excisions will be less frequent.

The sacroiliac joint is often complained of by

women, whose spondyroses have separated during pregnancy; I maintain that the requirements of such a diagnosis include: first, a confirmatory x-ray plate; second, a full measure of relief by the application of a plaster spica, or a sacroiliac belt. So many diagnostic sins are committed in the name of this interesting joint! A traumatic separation of this articulation is possible, but rare. To illustrate: A medical acquaintance, 6 feet tall, and weighing 250 lbs., tried to lift a calf out of a gully into which the creature had wandered and became wedged. He braced himself with one foot on either bank, and pulled; the calf did not budge, but his right sacroiliac joint did; the doctor was in bed for six weeks, and required a plaster-of-paris spica for a long time afterwards. A third-class of lesions of the sacroiliac articulation comprises those of bone or joint disease, and I hold that it is permissible to establish the diagnosis only when the x-ray or an incision demonstrates them. An interesting case was seen recently. A man of 36 complained of sudden pain just above the hip, and radiating into the sacroiliac joint. He noticed it first while exercising. This case proved to be a sarcoma of the iliac bone, and the man died in three months from metastasis in the dorsal spine. It was difficult to exclude myeloma until the examination for Bence-Jones albumose was found to be negative. Although the Wassermann test had once been positive, treatment had no effect whatever.

Needless to mention, all cases of backache should be examined as to their stature and gait, all clothing being removed; then one should invariably test the mobility of the spine. Other elementary essentials are tests of the nervous and urinary systems, thoracic, abdominal and pelvic organs; the teeth should be inspected, as well as the upper respiratory passages. It is well to scrutinize carefully the hips, knees, feet, and hands. The feet may be deformed or flat; the hands may show the telltale evidences of osteoarthritis or gout. When in doubt, do *not* "use potassium iodide," but order x-ray plates of the spine, complete examinations of the blood, and a survey of the endocrine gland system. Occasionally one finds the need of doing all these things twice, for even the gynecologist and the proctologist are not infallible.

In closing this impressionistic survey of some of the milder forms of backache that belong to the

1. Memories of a wood-cut of a man with the blues, stooping forward with one hand on his back; a look of anguish is on his brow, advertising pink kidney pills in a yellow journal.

2. Woman, ditto, advertising a pink vegetable potion, 14 per cent. alcoholic content. Form letters sent free to all who write for advice to a nice old lady, long deceased.

3. Articles, without wood-cuts, next pure reading matter, full column, released by high-priced advertising agencies, laden with glittering generalities about the awful effects of spinal displacements, and their wonderful cure "by adjustment."

4. The science stage—no advertising, but spread by word of mouth at experience meetings. Symptoms are related with much gusto and in great detail. Patient herself holds the stage, including the spot-light.

6. Furnish to suit; the assortment is large.

7. Let us hope that the seventh age will last as long as the civilized world endures, that it may have for its slogan, "See your doctor first." For then the family medical adviser will meet the requirements of a safe and sane diagnosis, and institute logical treatment based thereon.

15 WEST FORTY-FOURTH STREET.

CASE OF SYPHILITIC DACTYLITIS, WITH X-RAY FINDINGS.

BY JOSEF SEILIN, M.D.,

CHICAGO, ILL.

PATHOLOGIST, LAKE VIEW HOSPITAL.

K. J., colored, age 22, single, laundress, consulted me December 1, 1920, for pain and swelling in the right thumb of about a week's standing. She stated that her mother had had several living children, several miscarriages, and a still-birth. Her own past history showed her to have been in fair health, having had the usual diseases of childhood and no other serious illnesses. However, on questioning, she admitted the possibility of venereal infection. She also had had nocturnal headaches, tibial bone pains, and shortness of breath, with oppressive sensations beneath the sternum on exertion.

Examination gave the following data: Well-nourished, well-built female, palpable glands in the posterior cervical region on both sides and with epi-

domain of the orthopedist, may I not recall seven stages of the popular beliefs in regard to backache cures? They are the consequence of a habit of reading all of the newspaper, including the advertisements.

trochlear glands on both sides, the axillary glands were small but palpable; the inguinals large on both sides. Mouth negative; chest negative except for heart findings as follows: enlargement of left ventricle, loud systolic and diastolic murmur in aortic

area, and an arrhythmia which on closer investigation proved to be a partial heart block with an occasional ventricular extrasystole. The ascending and transverse aorta were markedly dilated. Abdomen was negative. The tibiae had palpable nodules on the crests. Reflexes and sensation tests negative. The right thumb was swollen on the volar aspect at the interphalangeal joint and slightly red. It was extremely tender, painful on motion, and also hurt somewhat even at rest. Urine negative. Routine blood negative. Wassermann of blood positive. An x-ray picture of the thumb showed a proliferative periostitis on the volar aspect of the interphalangeal joint. The bony nodules seemed to be deposited in the synovial sheaths and tendons besides the periosteum itself. The series of pictures reproduced show the condition at beginning of and during treatment. She was put on ascending doses of potassium iodide and mercury protiodide by mouth. The pain and tenderness disappeared in about five days, and the swelling gradually went away in the course of a month. The x-ray pictures were made on the following dates and show the changes in the bony deposits: December 1, 10, 17, 25, and 29, on which date the joint looked practically normal.

4420 CLARENDON AVENUE.

PHYSICAL THERAPEUTICS IN NEW YORK HOSPITALS.

By A. B. HIRSH, M.D.,

NEW YORK.

ONE of the notable changes in the attitude of the medical profession since the recent war is the growing tendency to add physical methods to its other means of treatment, an advance that applies with especial interest to practitioners in North America. Information from various sources shows a widespread awakening in this direction. True it is that in former years some few confrères, in scattered localities, did employ various physical modalities or, if not trained in their use, would for this purpose send patients to non-medical persons with more or less knowledge of this or that phase of the subject. But the interest of doctors, as to its importance, was usually aroused only as some one physical method affected their particular field of practice. Fulguration of intravesical neoplasms by the urologist is an instance.

It was probably only lack of opportunity to obtain accurate data and training in this branch of rational therapeutics that had until recently created a feeling of indifference, if not of mild antagonism, for it within professional ranks generally. Curiously, what seemed inconsistent in leading practitioners here was the fact that they had for years been referring seriously ill patients to European spas and specialists; then, when such patients returned much improved or cured, following resort to certain physical means, little or no effort was made to introduce the latter on this side of the Atlantic. Farsighted men have often given voice in protest at this attitude. "The physician who simply cures his patient without giving heed to the functional result obtained or to the future employment of the individual is falling short of his duty," in the opinion of Mock,¹ who also holds that "Physicians . . .

who, by careless methods, such as leaving the after-care of their patients to untrained assistants, persist in turning out injured workmen with permanent handicaps—such physicians must be reeducated or in some way barred from the practice of medicine."

There is no denying that American physicians, broadly speaking, in the absence of the subject from the medical school curriculum, had in prewar days been rather slow to realize the value of physical treatment measures. Because of such tardy recognition we are far behind our continental European brethren whose facilities in this direction have for decades been systematically utilized.* Not that pioneers to advocate adoption of these necessary treatment adjuncts were lacking; indeed, quite the contrary was the case as the medical schools were often called on to include teaching of these branches. But while undergraduate instruction, as is well known, had steadily advanced in standard within the past generation there seemed to be no room for introduction of physiotherapy in the curriculum.

On the other hand, the thirty years' efforts of the American Electrotherapeutic Association and its organ, *The American Journal of Electrotherapeutics and Radiology*, had done much in Canada and the United States to prepare the way to a more progressive view of the matter. Included in these efforts was application of the Roentgen ray to malignant conditions and dermatology which, starting in the first decade of this century, had further served to arouse curiosity among physicians as to additional physical treatment methods.²

It was the strikingly favorable results achieved in the physiotherapy service of war hospitals, however, when directed by experts, that made their permanent impression on (a) the many civilian practitioners who were officers, stationed at these large centers, and (b) the thousands of patients so benefited who together carried the news to all sections. Success was the rule with a great variety of serious conditions, usually chronic, medical as well as surgical, following the military life.³ To remove a seemingly permanent eye traumatism with accompanying mental hebetude by the direct current; to see an old empyema clear up under diathermy⁴ after repeated operative failures; to end a distressing paroxysm of asthma by three minutes of static effluve; to build up defective muscle action progressively by the sinusoidal current; to fill out tuberculous and other extensive surface ulceration by the ultraviolet ray after ineffective resort to other therapeutics; to stimulate subnormal metabolism by autocondensation, the static wave, diathermy, and the ultraviolet ray; to remove longstanding osteomyelitis and osseous non-union by diathermy with ample outpouring of osteoblasts⁵; these were but a few of the many convincing lessons taught. That medical officers often came themselves or sent members of their families for treatment will serve to illustrate the confidence inspired. It was this revelation that within two years had

*There is an extensive literature on the subject in most modern languages. International Congresses on Physical Therapeutics have been held at stated intervals—the first one since the war, in September last, at Antwerp. The proceedings at these meetings are always of high standard and its participants usually eminent scientists.

brought about, in the desire for progress in treatment, ideas that are epochal.

A factor of lesser importance in causing this change of view is a frank recognition of the situation that the public itself, no longer satisfied with mere prescription writing, surgery, etc., and insistent on physical applications with which but few medical graduates are acquainted, flock in considerable numbers to the various new cults—to the detriment, of course, of the ethical medical practitioner.*

It is of good promise, therefore, that the old-time professional prejudice fades gradually as physiotherapy, the collective term for the various methods discussed, is permanently established in the armamentarium.

Such physical measures are here implied to include treatment, under modern technic, by manipulation, exercise, water, heat, light rays of various kinds, electricity, mechanical apparatus, special games, and training in selective occupations. The day of empiricism in their application may be said to have passed, and their various indications in disease and injury are, as a rule, supported by laboratory tests, by standardization of apparatus, and by continually improving technic. Some of these measures have, of course, been given by adepts, according to one system or another, since the dawn of modern civilization. One need but mention, as instances, the jiu jitsu of Japan, massage and curative movements in Scandinavia, medical baths throughout Europe, etc. The recognized medical profession has for generations given its approval to these rational modes of treatment—more especially so, those abroad. What had, however, usually been lacking—at least, so far as concerned American practice—was a coordination of all of the established physical measures with each other and with treatment in general. What must be stressed is the fact that it was this important coordination that was brought about in some of the larger war hospitals, under direction of certain medical officers who for many years had restricted their civilian practice to this field.⁴

This is not the place to go into details of the various physical modalities, their indications in accident and illness, or their mode of application; the ground to be covered would be too vast for even a series of journal articles. Those interested may find dependable textbooks in the lists of leading medical publishers. There is unfortunately not as yet a comprehensive work in English dealing with the entire subject, although a series of manuals on *Physiologic Therapeutics*, edited by Solis-Cohen some twenty years ago, was a laudable effort in this direction.

Whether used apart or as an adjunct to older remedies, physiotherapy is daily being successfully

*The sudden large demand for the specialized apparatus needed for physiotherapy in war hospitals forced quick expansion of manufacturing plants that, to utilize their broadened facilities, in post-bellum days advertise extensively and urge doctors to use these appliances for various demands of every day practice. This, also, by repetition helps to spread a knowledge of the physical treatment methods. One of the world's greatest electrical manufacturing corporations has lately entered this field of commercial enterprise, a further indication of the probable increasing call by the medical profession for this class of products.

applied to the whole range of disease and injury, acute as well as chronic, and often where other means utterly fail. It is this fact that must be grasped by the entire profession.⁷ In New York, for example, it grows constantly in favor at the Manhattan State Hospital with its 6,000 cases of mental disease; likewise, for the patients who are usually aged or else worn in the industries, at the Montefiore Home; for the great variety of sickness and accident met among seafaring people in the U. S. Naval Hospital, and for the crippled and sick war veterans in Fox Hills and Polyclinic Hospitals.

Progressive specialists are well aware of its value and growing importance, and each specialty appropriates some one or more of its modalities, previously tried out by the pioneer physiotherapist.

The chief obstacle now preventing a more rapid spread of knowledge on physiotherapy here is the insufficient number of teaching courses available, either for the undergraduate or the full-fledged practitioner. Abroad, in addition to the lectureship at Oxford, professorships of physical therapeutics have been founded in the Universities of Ghent, Bordeaux, and Madrid. In Canada courses on the subject are given at Hart House, Toronto, and at McGill University. In the United States, according to information at hand, instruction is given in physical methods in Boston at City Hospital, at Harvard and at the Children's Hospital; and similar courses are given to New York undergraduates at the Montefiore Home; also, at the Jefferson and the University medical schools in Philadelphia. It is announced that physiotherapy is to be regularly included in the medical curriculum at the University of Indiana.

In the way of institutional postgraduate study courses, however, but little is as yet obtainable here; private instruction is the only resource at present. Ultimately hospital facilities must be at hand for the larger groups of physicians who are sure soon to find it necessary to add this knowledge to their other attainments. And for this end the hospitals of the metropolis, the main graduate teaching center of the country, must furnish the clinical and other needs. But where are the physicians to be found at present capable of giving this coordinated instruction?⁸ How soon will the great hospitals in New York be prepared to furnish these necessary physical treatment facilities for patients generally? Do their authorities realize that a nationwide agitation for introduction of a physiotherapy service is being carried on by American medical leaders—and what better opinion than that of Dr. Frank Billings who, during the war, was

*Just as in the war hospitals, the demands for physiotherapy for similar civilian institutions call for full-time, salaried medical directors with previous experience in the various phases of the subject. In this connection, an unusual opportunity to obtain such skilled men was missed when the advice of Cotton was neglected in February last. (Vide "The Need for War-Trained Physiotherapy Experts in the Hospital," by Frederic J. Cotton, M. D., Formerly Surgeon-in-Chief U. S. Army General Hospital No. 10, *Modern Hospital*, Feb., 1920, p. 101; also, the editorial, p. 119, on "Physiotherapy in the Hospital an Outcome of the War.") In this appeal the eminent New England surgeon urged that the specially trained physicians, then leaving army duty as provisional hospitals closed, be promptly engaged because of their extensive clinical physiotherapy service.

[illegible]

*Information supplied by a member of the visiting staff. At other institutions above data was given and all apparatus shown the writer by either the superintendent or by an interne or member of the staff, at the request of the superintendent. The plus-mark signifies that the method printed at the head of the column is utilized by the hospital named at the left-hand end of the horizontal line.

head of the Division of Reconstruction under the Surgeon General of the Army? Dr. Billings maintains that every hospital needs a physiotherapy department just as much as an operating room. The orthopedist's viewpoint has been given quite lately by Mock,⁶ also formerly active in the Army, who insists that "Inadequate medical and surgical care has been responsible for an appalling number of permanently handicapped individuals. . . . The knowledge that more than three times as many men and women were being disabled annually in industry as were disabled in our entire army has awakened the nation's conscience to the need of rehabilitating these unfortunates and of preventing such a casualty list. . . . Patients are discharged to convalesce outside to make room for more acute cases. . . . The lack of proper care during this stage of recovery often causes a relapse with re-

turn to the hospital, with all the needless economic loss which such a system incurs . . . physiotherapy departments in the hospitals with facilities for baking stiffened joints or contracting scars, or facilities for hydrotherapy and massage given daily will prevent many permanent deformities and will hasten recovery." Both Billings and Meek, among many others, thus voice the experience of practitioners familiar with the subject that a well-rounded physiotherapy service, separate from but on an absolute equality with each other department, is absolutely indispensable for any hospital claiming to be modern.

To study the local situation in this respect visits were paid to fifty hospitals throughout New York City, and five of these were found to have fairly complete arrangements for physiotherapy. The information thus obtained was then tabulated so as

to list the separate kinds of treatment in parallel columns, saving much needless description.

The results, as shown in the accompanying table, proved to be encouraging in prospect even if a little disappointing in number of institutions aroused to the importance of the subject. The brighter side of the outlook for advance in this direction is seen in the outfits, in daily use, in the larger hospitals. Even if some of the latter do lack important kinds of apparatus and, too, even if those in charge (because uninformed as to its proper use and value) do oppose its introduction, the fact remains that unmistakable progress has been made. Addition of a complete department of this kind is noted as a feature of almost all new hospitals planned to be erected. The authorities of several other large hospitals, now in operation, are at this time busy with the problem of installing such a service. With these advances assured, there can be no question but that all others must follow the precedent established. And with New York hospitals thus equipped, equal or superior to the best European standards, those elsewhere must follow suite, and thus a great betterment in treatment become permanent.

CONCLUSIONS.

1. Physical treatment methods, long viewed askance by the medical profession, are now regarded as essentials in practice. America has fallen behind Europe in their introduction.

2. The number of these physical modalities is a growing one, research study supporting their original empiric use, and their application is to the whole range of disease and injury.

3. Proper use of such agents calls for as well-rounded training as for any other special division of practice. Non-medical persons should apply such various agents when under direction of physicians recognized as authorities in this field.

4. Undergraduate instruction on the subject, at present found in a few centers, must soon be included in the curriculum of all medical schools. Postgraduate courses, now given only by private individuals, should become part of the work of hospitals everywhere.

5. Hospitals lacking physical treatment facilities, in charge of full-time medical directors, fail to give proper service to patients and can no longer be considered as modern. Some hospitals in New York have made a fair start in the new direction, but active propaganda may be needed to make medical staffs and directorates in general realize the urgent need for introducing these indispensable measures.

Bhang Smokers.—Briand and Livet have studied the Indian hemp smokers of Mauritius and generally speaking find them not different from the consumers of hashish. The *bhang* of the Anglo-Indian is known as *ganidin* by the French. The effects of cannabis among the Mauritians is comparable to that of alcohol in inciting to crimes of violence. Among the hemp consumers are found smokers, eaters, and hypodermists. The pipe used is especially designed for the purpose, being made of terra cotta with an opening for the stem close to the base.—*Le Bulletin Médical*.

HOW MAY WE REDUCE THE MORTALITY IN APPENDICITIS?*

By MAURICE KAHN, M.D., F.A.C.S.,
LOS ANGELES, CAL.

It is with a certain diffidence that I bring to your attention the subject of appendicitis which may seem to some too trite to merit discussion; but until the blemish is removed from our reproachful statistics, just so long is it necessary to call attention to the causes responsible for the results obtained, that the honor of surgery be not traduced.

Paterson¹ gives the mortality of appendicitis in the London hospitals at at least 10 per cent., and probably nearer 20 per cent. Murphy² gives the average hospital mortality in appendicitis as a little over 10 per cent. These figures are taken from the printed annual reports of hospitals which are progressive enough to publish reports. So it is safe to assert that the actual mortality in this country is much higher.

Kakels³ quotes De Quervain as follows: 1,723 cases operated upon on the first day of illness with mortality of 0.69 per cent.; 1,389 cases on the second day, 4.7 per cent.; 788 cases on the third day, 10.7 per cent.; 1,197 cases on the fourth and following days, 21.2 per cent.; giving a total of 5,097 cases with average mortality of 8.1 per cent. In the last two groups the patients reached the surgeon much too late, and doubtless some in the second group could have been diagnosed earlier than they were. At any rate, there should be no third and fourth days of appendicitis, so at the least calculation, 1,985 out of 5,097 cases were late or mishandled cases.

Kakels³ also quotes Van Arx as reporting: 162 cases without perforation, 1 death, 0.62 per cent. mortality; 70 cases with localized abscess, 10 deaths, 14.25 per cent. mortality; 58 cases with general peritonitis, 31 deaths, 53 per cent. mortality. Here we have 128 neglected cases out of 290, or 44 per cent.

Turner⁴ states that 40 per cent. of his cases reach him when the inflammation is no longer limited to the neighborhood of the appendix.

Wood⁵ reports 221 cases, with a mortality of 5.88 per cent. There were 90 cases without peritoneal involvement without a death, 10 abscess cases without a death, 121 cases with peritoneal infection with a mortality of 10.74 per cent.

Morf⁶ recently reported a series of 822 cases operated on by the staff at Cook County Hospital, with a mortality of 58, or 7 per cent. There were 266 cases with abscess and 26 cases of diffuse or general peritonitis, making 292 tardy cases, or 35 per cent.

My own series of 307 cases show practically the same proportion of late cases; in fact, it was this large percentage of advanced cases in my own practice that prompted me to investigate the experience of other surgeons. Ninety-three were acute, average time since onset, 24 hours, no deaths; 19 local peritonitis, 30 hours, no deaths; 74 gangrenous, 38 hours, no deaths; 35 diffuse peritonitis, 3½ days, 6 deaths; 86 abscess, 4½ days, 3 deaths. One hundred of these patients gave a history of hav-

ing had one or more previous attacks. That is to say, one-third of the patients comprising this series required repeated warnings before consenting to operation. Practically 40 per cent. are late cases, indicating that in 40 per cent. some one blundered—the patient, a relative or friend, or the doctor who first saw the patient.

These figures are appalling and in contemplating them one's first thought is apt to be one of incredulity; or if one be not actually incredulous, perhaps the statistics are thought to be gathered from communities in which men of mediocre attainments are practising. Or again, one may be consoled with the specious notion that an analysis of his own cases would not disclose any such dissatisfying picture. We are all too prone, I think, to dismiss the subject with the satisfied feeling that we are doing all that is required. But so long as 10 per cent. mortality or higher exists, we are manifestly not doing our full duty. Is surgery at fault? By comparing the figures it is noted that practically all cases operated on in the first twenty-four hours recover; but the mortality rises progressively after that time. So the conclusion is forced on one that surgery is not culpable, but acquits herself creditably if given a fair field. Procrastination which permits cases to develop complications is the cause of death in this disease. One may state, indeed, that a case of appendicitis that has progressed to the stage of abscess formation indicates that some one has mismanaged. Knowing then as we do that scarcely one out of a hundred cases of acute appendicitis operated on during the first twenty-four hours is lost, it becomes important, in order to reduce our present mortality to a reasonable and proper percentage, that the patient should be operated on within this twenty-four hour period, the earlier the better. This in turn requires an early diagnosis; hence, it follows that the fate of the patient rests with the physician who first sees him.

Possibly the diagnosis is frequently missed in its early stages because the general practitioner sees many simple cases of indigestion, whereas he is seeing comparatively few of appendicitis, so perhaps he gets the habit of assuming cases of abdominal pain to be simple until proved serious. This assumption would also explain the frequency with which cathartics are given in these cases. It were better, however, to assume every belly ache serious until proved simple. This attitude should result in eliminating cathartics with their power for harm, and the substitution therefor of the harmless enema. This would be a long stride in advance and would of itself reduce the mortality appreciably.

Just a word about vomiting, as I feel that many cases have not been diagnosed as early as they should have been, merely because this symptom was lacking. Too much value should not be placed on this sign, as not all patients with appendicitis vomit; in fact, one may have peritonitis well advanced without vomiting. Even nausea, which results from the same stimulus as that causing vomiting, only milder in degree, is not always evident. The symptoms are, however, so generally comprehended that there is little excuse for failure to make an early diagnosis. But should doubt exist regarding the diagnosis, I would recommend surgical consultation rather than await the possible spread of infective

*Read before the Los Angeles County Medical Association.

processes to certify it. Here let me venture the opinion that physicians would obtain more satisfaction from surgical consultation, and tardy operations would become less common, if they would develop the habit of calling surgeons while the diagnosis is still doubtful, instead of waiting till the diagnosis is clear and then calling a surgeon for the operative work only. Neither the laity nor the physician should have the idea that surgical consultation is invariably followed by operation. Incidentally, there is nothing that contributes at once so much pleasure and profit to practice as frequent consultation with men of integrity and discernment.

Further, it is regrettable but true that some doctors still adhere to the notion, very prevalent fifteen or twenty years ago, that all acute appendicitis cases are alike, in that they tend to progress in a uniform manner; that operation between the third and seventh days is particularly fatal, and should not be performed until the inflammation shall have been localized by nature's own defenses. They maintain that those cases that die without operation during this period of spreading infection would also have died with it. This form of reasoning fails to convince me; in fact, for fifteen years I have searched in vain for evidence supporting this theory; and until the advocates of this method shall have produced statistics proving that a greater number of these cases are saved by this method, my conscience refuses to be sung to sleep by this sophistical lullaby.

There are also some medical men, who for one reason or another, the importunities or rebellion of family or friends, or what not, permit their judgment to be impaired, and temporizing measures are instituted, thus granting a respite from surgery, and this despite the teachings of Osler who fifteen years ago said: "There is no medicinal treatment of appendicitis." For instance, a mild attack of appendicitis, which begins with colicky pains, nausea and vomiting and a slight elevation of temperature, may develop a leucocytosis and local sensitiveness in the right flank in the first six or eight hours. Twelve to eighteen hours later the pain and fever have disappeared. The doctor is then in a quandary which his own procrastination has matured. He is unable to tell whether the patient is going on to an uneventful recovery, or headed straight for the grave because the infected appendix has undergone complete gangrene.

There is only one treatment for appendicitis—surgery. Inasmuch as the progress of a given case defies prophecy, there is only one time to operate—now. In other words, a diagnosis of appendicitis should be followed immediately by operation.

To summarize briefly: Reliable statistics show a mortality of from 10 to 20 per cent. in appendicitis.

Sixty per cent. are early cases in which the infection is within the confines of the appendix, and these betray practically no deaths.

Forty per cent. of those operated on are late cases, *i. e.* the infective process has spread beyond the confines of the appendix and it is this class which gives us our mortality. This present high mortality can be greatly reduced by timely intervention, but early diagnosis is essential in order that early operations may be performed.

A CONCEPT OF X-RAY PATHOLOGY.

XII. GASTROPATHY.

By A. J. PACINI, M.D.,

WASHINGTON, D. C.

CHIEF OF LABORATORY AND X-RAY SECTION, HOSPITAL DIVISION,
U. S. PUBLIC HEALTH SERVICE.

(Concluded from page 701.)

Gastrospasm.—In the x-ray pathology of the stomach the law of contrary innervation plays a more prominent rôle than is the case with the esophagus. In fact, the law of contrary innervation seems to be more accentuated as the distal end of the tract is reached.

Spastic phenomena in the stomach require careful observation and study. They may be divided into two types, according to the origin of the irritation causing the spasm. First, the extrinsic, and, secondly, the intrinsic phenomena.

Extrinsic incitants result from abnormal conditions arising outside and away from the stomach, often remotely removed. They are less frequent than in intrinsic spasms. Gastrospasm is evidenced by a disturbance in the form, size, outline, and position of the organ. One form of extrinsic gastrospasm is that in which an incisure appears in the wall of the stomach, usually in the pars media, and progresses to the pars pylorica, greatly resembling a giant peristaltic wave. The appearance of this phenomenon is usually intermittent. Another form is that in which the gastropacity assumes an "hour-glass" form which may persist during the entire time of the examination or may relax at any moment. In the pyloric end a spastic filling defect is often reflexly produced, particularly when evoked as a result of accumulation of the ileopyloric reflex of Barclay. Cholecystitis and chronic appendicitis induces a spasm of the pyloric sphincter.

Extrinsic spastic manifestations, though generally localized and regional, may sometimes affect the entire gastric musculature when it is manifested as hypertonus far exceeding the usual normal physiological limits and rendering the stomach contracted, inert, and tense. The subject of extrinsic gastrospasm is summarized by saying that it may manifest in a manner oftentimes precluding the possibility of absolute differentiation from gastrospasm that results from intrinsic cause.

Carman summarized gastropastic manifestations of intrinsic reflex as follows:

1. Displacement of the stomach upward and to the left.
2. Diminution of gastric capacity.
3. Small size of the gas bubble and small amount of secretion.
4. Tardy canalization.
5. Lessened mobility and flexibility of the stomach.

6. Disturbance of peristalsis: (a) diminution; (b) exaggeration.

7. Disturbance of the pyloric function: (a) gaping of the pylorus; (b) spastic contraction of the pylorus.

8. Incisura production and hourglass form of the stomach.

9. Deformity and pseudo filling defects of the gastric contour, either local or general.

Gastrospasm of intrinsic cause is most generally produced by ulcer and less frequently by cancer. Spasm due to gastric ulcer may present as an hourglass incisura of the stomach; a diffuse spastic distortion; or a spasm of the pyloric sphincter.

When the indentation is the result of ulcer it is persistent and permanent as to situation and at once suggests the character of the lesion responsible for the spasm. Gastric ulcer may occasion a diffuse spasm involving much of the pars pylorica, whether the ulcer is situated in the pars pylorica or in the pars media. When in this latter location a six-hour retention frequently accompanies the x-ray pathology. Cancer of the stomach may, through the irritation that it incites, also occasion gastrospasm.

When the case presents gastropastic irregularities in its radiopacity the x-ray pathology should determine whether the irregularity is due to an organic lesion producing gastrospasm in its immediate locus; whether the spasm is due to a lesion in the stomach located other than at the site of spasm, or whether the spasm is the result of an abnormal irritation reflexly referred to the stomach from some other locality.

Gastric deformity due to organic lesion presents the following characteristics: (1) persistency, (2) constancy of location, (3) repeated similarity. The deformity does not disappear after the administration of an antispasmodic. The mass responsible for the deformity may sometimes be palpated under the screen. There is usually associated with the deformity a typical crater or niche.

If spasm results directly from an ulcer or cancer in the stomach it manifests generally at the level of the involvement in the area opposite the site of lesion. Its appearance may vary in repeated examinations, but the presence persists. The deformity is not dispelled after administering antispasmodics.

Gastrospasm reflexly produced is usually brief. It may not be persistent as to locus. It is dispelled under the action of antispasmodics.

The administration of atropine forms the most practical test for the differentiation between reflex and intrinsic gastropastic phenomena. In employing antispasmodics it would seem the best practice to administer tincture of belladonna, the roentgenologist being guided by the physiologic effect produced. An arbitrary dose is not recommended, but rather repeated therapeutic doses should be given until the throat dries, the skin flushes, and the pupils dilate. Unless the antispasmodic physiologically operates, its administration is without effect on the gastrospasm and will lead to error in conclusion.

Gastric Cancer.—The x-ray pathology of gastric cancer rests with determining the presence or absence of gastric tumor. As Graham has indicated, benign tumors of the stomach are rare, nearly 95 per cent. of gastric tumors being cancers. Also, practically always erosions encroaching on the gastric lumen are malignant.

Carman shows that about 70 per cent. of all gastric cancers occur in the pyloric end of the stomach, while 90 per cent. of all gastric ulcers occur on the lesser curvature and posterior wall.

The x-ray pathology of gastric cancer includes abnormal departure in the contour, pyloric action, peristalsis, motility, position, and size of the stomach.

The basic x-ray sign of cancer is a filling-defect in the stomach lumen. This results from the extension into the stomach space of the tumor. Permanent irregular filling-defects are strongly suggestive of carcinoma. The defect should show no change in location or appearance on repeated examinations after palpatory manipulation or the administration of antispasmodics.

Filling-defects may result from causes other than cancer, the most common being faulty media (improperly opaque meal), secretion in the stomach, food remnants, and miscellaneous stomach pressures from without. But these are not permanent either as to persistence or form on repeated examination or after administering antispasmodic.

Altered pyloric function generally accompanies cancer. The pyloric antrum may have a sphincteric interference resulting in infiltration and stiffening so that the pyloric pars media may bulge and give the appearance of gaping. Pyloric obstruction resulting in a six-hour residue accompanies about 60 per cent. of gastric cancers, the amount of residue varying, of course, with the degree of obstruction.

Perversions of peristalsis, retardation, or acceleration in the emptying time of the cancerous stomach, fixation of the stomach, occasionally, diminished flexibility of the viscus (especially in scirrhus type), persistent gastrospasm, alterations in the size and capacity of the stomach, all are evidences conducive to the x-ray inference of gastric carcinoma.

Usually before the patient complains of symptoms incident to gastric carcinoma the extent of malignant invasion is such as to permit the ready detection of the lesion through the use of x-ray study. It is important that early cancer be detected. The x-ray pathology of early cancer is less defined than that of advanced malignancy. Its detection depends upon the character of the malignancy, whether an outspoken tumor or an insidious infiltration, its locus and the amount of corroborated x-ray pathological evidence weighed against the clinical findings. If the cancer is frankly tumorous its projection into the gastric lumen is manifested by a filling-defect which may be smaller than one produced by more advanced cancer, but shares every characteristic of the filling-defect of advanced malignancy; so that the true test in the x-ray pathology of cancer lies more in the permanency rather than with the size of the filling-defect ulcers undergoing cancerous degeneration present x-ray signs that can be differentiated from ordinary ulcer.

Gastric Ulcer.—In the x-ray pathology of ulcer there are two types of signs: those that are primary and virtually pathognomonic, and, secondly, those that are secondary and corroborative, but nevertheless diagnostic.

The pathognomonic signs of ulcer include the niche, the accessory pocket and the hour-glass stomach. The niche is a visible ulcer crater which has become filled with opaque meal. It appears as a

bud-like diverticulum on the outline of the stomach. Often the niche is not revealed unless the stomach has first been subjected to lavage for the purpose of removing food remnants that may remain lodged in the pocket. It is characterized, as a sign of gastric ulcer, by its undeviating persistency in locality. The accessory pocket results from perforation of an ulcer, and is also characterized by persistency in location. Hour-glass stomach occasionally follows as a sequence to perforated gastric ulcer. It cannot be distinguished on the x-ray plate from the spastic contraction due to other origin excepting by the antispasmodic test and by the presence of concomitant signs. The contributory signs of ulcer include spastic manifestations, incisures, six-hour meal retention, hypotonus, peristaltic alterations, localized tenderness, and impaired mobility. Of these, the six-hour residue, incisure, hour-glass, and diffuse spasm are important secondary manifestations strongly suggesting ulcer.

Duodenal Ulcers.—The x-ray signs of duodenal ulcer may be direct or indirect. The direct sign is the absolute visualization of a deformity of the duodenal cap. The important point in connection with diagnosing duodenal ulcer from bulbous duodeni distortion rests with making certain that the defect truly represents an actual irregularity in the scar tissue incident to the ulcer and resident in the cap and not an irregularity due to artefact. A duodenal ulcer may vary from a simple to a perforating lesion. If the ulcer is simple or superficial the emptying time of the stomach is normal or decreased in contrast to the delayed emptying time in cases of gastric or pyloric ulcer. If the ulcer is puncturing, which is less frequent, in addition to the symptoms of superficial ulcer, it presents a characteristic diverticulum which persists after the rest of the duodenum is cleared of barium. The indirect signs may be grouped under the convenient mnemonic triad of "hypers"—namely, hypertonus, hyperstalsis, and hypermotility. (Carman.) In the diagnosis of duodenal ulcers the use of the silk string test is greatly recommended. If the silk string test shows blood at exactly the site where a persistent duodenal deformity is visualized on the plate or screen, the evidence is strongly in favor of a positive diagnosis.

Duodenal Cancer.—Cancer of the duodenum produces little x-ray evidence, if any, that is pathognomonic of the condition. Perhaps the most constant and important x-ray finding is the gas and fluid distension of the bowel. Obstruction may present leading to dilatation of the stomach and decided retention after six hours and even twelve and twenty-four hours.

Differential Diagnostics of Stomach Diseases.—Diseases of the stomach may be classed as inflammatory, neoplastic, motor, neuralgic, anomalies in position, and foreign body inclusions. The inflammatory gastropathies may be primary or secondary. Primary gastropathies affect the physiologic activity of the viscus as the result of derangements primarily inherent in that organ; whereas secondary gastropathies result from conditions in which the stomach suffers because of encroachment upon it by extraneous pathology.

Gastritis.—Gastritis may be acute or chronic. Acute gastritis is hardly an x-ray entity; and the only significant x-ray pathology incident to an acute

gastritis is that that results from the symptoms of delayed motility. The x-ray is useful in differentiating acute gastritis between conditions that are sometimes mistaken for it. The conditions are gall-stone colic, appendicitis, gastric or duodenal ulcer, acute peritonitis, acute pancreatitis, gastric crises of locomotor ataxia, nervous gastralgia, and angina pectoris. The differentiation should be a clinical one and never so confusing as to demand x-ray aid.

Chronic gastritis may be primary or secondary in form. When primary it results from improper treatment of the stomach itself through dietetic errors, hasty eating, and similar faults. The secondary form accompanies various organic diseases, such as carcinoma, tuberculosis, cardiac insufficiency, and others.

The mucous membrane may swell, its surface become granulated, or polypi may form, and, later, connective tissue may proliferate, when the condition is known as hypertrophic catarrh; or there may be an atrophic catarrh with primary atrophy of the gland, thinning of the mucous membrane, and subsequent dilatation of the stomach.

In the hypertrophic form the contraction of the stomach that follows connective tissue proliferation is known as cirrhosis of the stomach, as leather-bottle stomach, or as Brinton's linitis plastica. When the stomach lumen is encroached upon by the thickened walls, owing to linitis plastica, the resulting microgastrica is readily demonstrable by the x-ray.

Chronic gastritis must be differentiated from gall-stone, chronic appendicitis, dilatation of the stomach, cardiopneumosis, gastric ulcer, carcinoma, pancreatitis, and infection of the bowel passages. The dilatation and ptosis are at once recognized by the x-ray; the gastric ulcer and carcinoma may be identified under careful serial x-ray plate study.

Achylia gastrica may be benign or malignant, for which differentiation the x-ray is invaluable. In the benign form the motility of the stomach, if impaired, generally shows hyperactivity; from which it is distinguished from the malignant form, wherein hypomotility presents.

Dilatation of the Stomach.—This may be acute or chronic. The acute form is rarely referred to the x-ray laboratory for examination, but when it is, simple fluoroscopy of the abdomen will reveal the gas-distended stomach in a manner that is unmistakably diagnostic. No previous preparation of the patient is required. Chronic dilatation may be intrinsic or extrinsic in origin; extrinsic when there is an obstruction at the pylorus due to the cicatrization of an ulcer, hypertrophic stenosis of the pylorus (either simple or cancerous), congenital stricture (particularly in children), or occasionally by pressure of a tumor from without; intrinsic when there is a relative or absolute insufficiency of the muscular power of the stomach. Atonic dilatation is characterized by the apparent lack of limit to the capacity of the stomach. It shows on the x-ray plate as an enormous sac. Dilatation due to pyloric obstruction likewise manifests as an enlarged gastric radiopacity; but it differs from atonic dilatation in that in atonic dilatation there is a loss of gastric irritability which sometimes persists in the dilatation incident to pyloric obstruction.

Gastric Ulcer.—Gastric ulcer has already been discussed in part. When considered in connection with

the clinical history, the age and sex of the individual form important criteria. The clinical diagnosis depends upon the cardinal symptoms of pain and hematemesis. The x-ray diagnosis depends upon visualization of the actual gastric defect as previously outlined. When the pain is exactly over the site of gastric defect, as can be determined by fluoroscopic examination, and the string test referred to shows the origin of hematemesis to be located at the point of gastric defect, the triad of signs (pain, defect, blood) is pathognomonic of gastric ulcer. The conditions that are to be differentiated from gastric ulcer are appendicitis, disease of the gall bladder and ducts, gastric neuroses, gastritis, gastric crises, and carcinoma. The x-ray diagnosis of appendicitis will be considered further on in these studies. The important differential rests between malignancy and simple ulcer. The x-ray differential has been discussed above.

Specific inflammations of the stomach are rare. They include syphilis, tuberculosis, glanders, actinomycosis, anthrax, and typhoid; and of these syphilis of the stomach is more likely to be found than any of the others.

Syphilis of the Stomach.—It is, of course, difficult to differentiate diffuse fibrous infiltration of the stomach from syphilitic infiltration by roentgen methods alone. The term "leather-bottle" stomach, applied to the chronic inflammatory thickened stomach wall, appears to be derived more from the consistency of the wall rather than from any resemblance to modern leather water bottles. Syphilis may manifest in the stomach in one of three types: simple syphilitic gastritis, syphilitic ulcer, or syphilitic hyperplasia. In the hyperplastic form the x-ray findings include deformity and diminution in the size of the stomach, compensatory dilatation of the esophagus, and gaping or obstruction of the pylorus. The stomach deformity may also be the result of intensive salvarsan therapy. LeWald mentions the rapidity with which the stomach empties itself, as observed particularly under the fluorescent screen, in cases of syphilitic gastritis. The diagnosis of gastric syphilis is arrived at through the conjoint effort of the clinician and roentgenologist, rather than through the x-ray findings alone.

Neoplastic Gastropathies.—Of these, cancer of the stomach, common between the ages of 40 and 60, is the most usual etiology of a gastric new growth. The x-ray signs of cancer vary according to the location of the lesion. If the cancer is in the pars cardiaca the symptoms are those of painful deglutition of solids marked with regurgitation; delayed esophageal passage of opaque meal, and stenotic encroachment by a tumor mass in the pars cardiaca. If the cancer is at the pyloric region there are accentuated peristalsis, markedly impaired gastric motility, and irregularity or filling-defect accompanied by tumor mass in the pyloric area. If the cancer is in the pars media, it is accompanied by an achylia gastrica, which tends to increase the motility and, therefore, overbalances the tendency to stagnation induced by the cancer, so that the emptying time or total motility is not impaired. The peristalsis is altered; the x-ray shows a constant filling-defect in the pars media.

Sarcoma of the stomach is exceptionally rare. When it occurs, its x-ray findings simulate gastric

cancer. It can be differentiated sometimes only on the score of the patient's age, sarcoma occurring most usually in young persons.

Disturbances of Motility.—Motor insufficiencies of the stomach may be manifested by inadequate peristolic movement. The stomach wall fails sufficiently to contract around its contents and, because of the weight of the included meal, it may become dilated (atonic dilatation). The contents of the stomach are emptied into the duodenum by means of the peristolic activity; and if this is injured the condition is one of motor insufficiency. Motor insufficiency is usually accompanied by atonic dilatation, though the two conditions may be separate.

Gastric atony may be (1) a part of a constitutional defect; (2) secondary to general diseases; (3) due to frequent overloading of the stomach, or (4) reflex, as in cholelithiasis or chronic appendicitis. The x-ray studies are directed to the motility test, the delay in the emptying time of the stomach, and to the abnormal filling of the stomach observed under fluoroscopy.

Secondary motor insufficiency of the stomach may be due to (1) a scar of ulcer; (2) perigastritis; (3) pylorospasm; (4) hypertrophic pyloric sphincter. If the motor insufficiency results from a malignant cause it is generally due to a carcinomatous obstruction at the pylorus. The x-ray findings include markedly intensified peristalsis often amounting to gastropasm. The dimensions of the stomach are demonstrably increased. The motility is impaired so that a residue is found after six hours.

Anomalous Positions of the Stomach.—When the stomach is posed abnormally low in the abdomen the condition is known as gastroptosis. This may be accompanied by enteroptosis and even a general visceroptosis. In gastroptosis the pylorus occupies a lower level than normal, there being a marked elongation of the main mass of the viscus.

In connection with gastric ptosis, which should remind of LeWald's water-trap type stomach, the important position that the roentgenologist must take is that of including a statement of the functional activity of the organ besides the statement of its position. A stomach of exaggerated fish-hook type hanging low in the abdomen may be described as to position; and, while its form represents that generally assumed by water-trap type stomachs, it may not be termed a water-trap type stomach unless extended x-ray investigation shows that at the end of six hours or longer an actual retention of fluid foodstuff is trapped in the organ. That is, water-trap type stomach is not a water trap unless it actually retains fluid for longer than the usual permissible time. If the roentgenologist includes a statement of the functional activity of the stomach, to which he is justly entitled, there need be no unnecessary apprehension regarding the condition of gastroptosis.

Nervous Gastropathies.—Of the sensory neuroses of the stomach the most important are nervous gastralgia and gastric hyperesthesia. There is nothing of x-ray certainty in the diagnosis of these conditions. The principal motor neuroses include atony, cardiospasm, and pylorospasm. These have already been discussed. There are nervous anomalies affecting the secretion of the stomach; and, while the secretory test often aids in inferring the presence

of a nervous gastropathy, the x-ray is of limited value in their study.

Foreign Bodies.—Foreign bodies in the stomach include particularly hair-ball. A hair-ball is readily visualized after the barium meal and persists for some time.

In closing a discussion of gastropathy and duodenopathy there should be mentioned the condition of congenital pyloric stenosis. In this condition LeWald has experienced extensive observations. The summary of x-ray pathology of pyloric stenosis rests with finding an enlarged gastric outline, a slowly emptying pylorus, and a residue that persists for a time, depending upon the completeness of the stenosis. Delayed emptying time in the stomach in young infants should always lead to the suspicion of the presence of congenital pyloric stenosis.

Often the roentgenologist is called upon post-operatively to survey the stomach with the view to ascertaining the operative success. The examination is conducted exactly in the manner that would be pursued in the usual gastrical survey, especial attention being paid to the patency of the stomach in the case of intestinal anastomoses.

OBSERVATIONS ON THE TREATMENT OF INCOERCIBLE VOMITING OF PREGNANCY.

BY GEORGE G. VAN SCHAICK, M.D.,

NEW YORK.

VOMITING of pregnancy may be of so intense a character as to place the prospective mother's life in jeopardy and form one of the few complications justifying the emptying of the uterus before term. In its most severe character the condition is a rather rare one and the practitioner must be very sure not only of the probable persistency of the trouble but also of the fact that it constitutes a real danger to mother and child before he decides to produce an abortion. I have seen a woman drool for months and apparently vomit all she took and yet, apparently by sheer force of will, go on to term and be delivered of a viable child.

In the treatment of a few of these cases, in the last three years, the writer chanced upon a measure that gave relief very rapidly and which appears to deserve trial at the hands of men having larger opportunities for observation.

CASE I.—Mrs. McC., born in U. S., a rather stout and strong woman, aged 26. States that three years ago she became pregnant. At this time she was living in California. At the beginning of the third month of pregnancy she was vomiting persistently and lost weight so rapidly that her medical attendant feared that further delay was dangerous. After consultation he decided to empty the uterus. Within a very short time after this had been done the patient regained her normal condition. Some months later she came to New York, where the writer treated her for minor ailments. She soon stated that she was most anxious to bear a child and asked about the possibility of becoming pregnant without having to go through the same ordeal again. The answer was that a second pregnancy might not bring symptoms as severe as in the first instance, and that if they occurred some means of relieving them, at least to some extent, would probably be found.

In March, 1919, the patient sent for me and told me that she was pregnant. She was then having nausea of pregnancy of moderate severity, for which the usual remedies were prescribed without much effect. A week or two later the vomiting rapidly became of extreme severity. No liquid or solid appeared to remain in her

stomach for more than a few minutes. By April 4 the patient was rapidly becoming emaciated and told me that, if anything, her condition was more severe than it had been in California. Of all her symptoms thirst appeared to trouble her most. Water at any temperature, champagne, aerated waters, lime water in milk or water, milk, pure or peptonized, whey, etc., were all rejected as soon as taken. In spite of this the patient asserted that she would undergo anything if only she could be kept alive long enough to have her child. As soon as the thirst became severe enemata of saline solution were ordered, to be repeated several times a day. This afforded some relief, but was soon replaced by the Murphy drip, used persistently for many hours day and night. The very capable nurse in charge took great interest in the case, and I suggested colonic washings twice a day. By April 20 the patient was beginning to retain water and peptonized fluids. On the 26th she ate and retained eggs, broth, and milk in liberal amounts. The vomiting had stopped entirely, to such an extent that there was not even a tendency to salivation. There was a rapid gain in weight and the patient felt so well that I did not see her again till May 29, and then for some trivial ailment. She declared that in the last four weeks she had only vomited twice and acknowledged that this seemed to have been brought on by some indiscretion of diet.

The pregnancy went on to term, with no further trouble, and she was delivered of an eight pound girl on December 4. At this time she is eager for another child and would welcome a third pregnancy.

CASE II.—Mrs. M. A. B., et. 31, walked into my office on November 1, 1919. I heard her retching in my waiting room. When she entered the office she presented a shocking picture of emaciation and looked so weak that I at once gave her some aromatic spirit of ammonia. She was at the time in the second month of pregnancy and gave a history of having had her uterus emptied twice on account of a similar condition. She was crying as she told me that she supposed she must lose this child also and that she had come to arrange for another dilatation and curettage. Her means did not permit of the employment of a trained nurse. I saw her in bed an hour later and personally washed out her colon, as far as such a thing may be done, and established a Murphy drip, giving directions to a sister for the continuance of the treatment and the preparation of peptonized foods. Three weeks later, when she walked into my office, I failed at first to recognize her, so great was the improvement in her appearance. She was delivered of a seven pound child on June 11, 1920.

CASE III.—In this instance the term "incoercible" can hardly be applied. Mrs. A. S., age 19, sent for me on January 15, 1920. She was two and a half months pregnant. She was vomiting from the time she awoke in the morning till the middle of the afternoon, on an average. After this she was able to retain a little water with a few drops of alcohol and a small quantity of milk or broth. Occasionally she could take a little white meat of chicken for supper, with dry crackers or toast or zwieback. Of this she usually vomited a little, but was under the impression that she retained some of the food. She suffered from constant hunger and thirst and had become so thin that her husband feared she had consumption. The patient was Jewish and exceedingly eager for a child. For a few days the usual remedies were prescribed with no visible result in abating her symptoms. Then she was put to bed and given colonic washings and the Murphy drip. Her condition cleared up entirely in about three weeks. After this she went to live in a suburb, where, I was told, she was delivered of a boy in July. As the symptoms in this case were far less severe than in the other two, it is possible that her pregnancy might have gone safely to term. At any rate, she was promptly relieved.

Whatever may be the principal factor in severe vomiting of pregnancy, whether toxemic, nervous, or due to some endocrine disturbance, it would appear that the supplying of large amounts of water, so that it is rapidly absorbed through the intestines, is capable of reducing the severity of the condition and enabling the mother to carry a child to full term.

HEMORRHAGE AND PERFORATION OF THE INTESTINE REMOTE FROM TERMINAL OCCLUSIONS.

BESIDES perforation of the cecum and ascending colon occurring in terminal occlusion of the large intestine, hemorrhages of the intestine may occur at a distance from the occlusion, whose cause must be attributed to the ulcerative process. The ulcerations, of which the hemorrhage or perforation merely represents a more advanced degree of evolution, are simple intestinal ulcers of inflammatory and not neoplastic origin, although the cause of the occlusion may be a malignant growth. These hemorrhages should be looked upon with suspicion, but one must not necessarily conclude that an intestinal neoplasm is present just because an elderly subject has a bloody discharge from the rectum, accompanied by constipation and notable emaciation.

Cecal perforations appear to have a more complex pathogenesis in terminal intestinal stenosis. The perforation may have a perfectly mechanical origin in which distention from feces and gas is the principal phenomenon, while degeneration of the muscular fibers of the gut plays a secondary part in the process. Secondly, there are perforations due to toxo-infection, in which the ulcerative process is of the first importance, the mechanical distention being merely an adjuvant factor facilitating rupture. Among the latter are those occurring during the evolution of chronic occlusion in which the intestinal walls, and especially the muscular coat, are greatly hypertrophied, and those which arise during acute occlusion following a long standing stenosis, in which the intestinal walls may be unchanged or even thinned. Usually these perforations occur after a long period of constipation, the result of a stenosis, but there are cases in which constipation is replaced by diarrhea obstinate to all treatment both medicinal and dietetic. The persistence of this diarrhea to the end of the last phase of the clinical evolution of the process, affords evidence of an enteritis added to the cause of the occlusion, a fact that has led some to suppose that in certain cases, at least, the cecal or colic ulcerations are not exclusively the result of coprostasis.

The symptoms of these cecal perforations, al-

though not different from those usually met with in ordinary intestinal perforation, nevertheless offer certain peculiarities which should be known. Although in some cases, the perforation gives rise to sudden stabbing pain and aggravation of the patient's general condition, it is undeniable that the most common condition is that of rather attenuated symptoms of general peritonitis. In the majority of cases the expression and pulse remain good for some time, the pain is so mild that deep palpation is necessary to awaken it, vomiting is apt to be bilious rather than fecaloid, and the temperature is about normal; but hypothermia—one of the principal symptoms of acute peritonitis—is absent in most cases. To the symptoms of occlusion, these very slight symptoms of peritonitis are progressively added, the symptomatic ensemble imparting to the clinical evolution such an indefinite and complex character that when operation is undertaken—and this is always done too late, for obvious reasons—the surgeon is surprised to find the abdominal cavity filled with fecal matter and often presenting the commencement of a reaction of the serous membrane, thereby proving that the perforation often dates back one or two days.

Since adhesions are almost invariably absent, the peritonitis is general and death is the outcome. The prognosis is always bad on account of the absence of adhesions which would otherwise set up a barrier to the infection, while on the other hand, the rupture having occurred in a segment of the intestine above the stenosis, the products emptied into the peritoneal cavity are unusually septic.

As to the hemorrhages resulting from cecal ulcerations, their symptomatology is evidently that of any intestinal loss of blood. Particular attention should be directed to the difficulty of diagnosing the site of the hemorrhage in these circumstances, because, considering that the stenosis upon which they depend is in the majority of cases a malignant growth in the terminal portion of the large intestine, they are almost fatally attributed to the cancerous ulceration whose diagnosis has been previously made.

MENINGEAL REACTIONS.

To give a description of the meningeal reactions would necessitate a review of the clinical history of all the bacterial cerebrospinal meningitides, but briefly the symptomatology is as follows. The onset of the process may be sudden or preceded by some prodromes, such as headache, fatigue, and anorexia. This prodromal phase is usually wanting, but when it exists it is so short and indistinct that it probably escapes notice. The temperature, with or without a chill, quickly attains as high a degree as in pneumonia or erysipelas, and remains high throughout the duration of the disease. Headache precedes, accompanies, or soon follows the appearance of the fever and is from the start intense and distressing. It has no special localization, makes sleep impossible, and provokes moaning even when

the patient is comatose. Vomiting is almost constant and typical of cerebral origin, that is to say it occurs without effort. Constipation is usually present during the first few days, but is not obstinate, giving way to a laxative. There is a disturbance of the intelligence and frequently a noisy delirium with hallucinations.

In children convulsions mark the onset of the affection; they are sometimes general, at others partial. Stiffness of the neck muscles and Kernig's sign are present in most cases. Paralyses are less common and preferably involve the muscles of the face and limbs. Disturbances of the sensibility also exist, characterized by hyperesthesia with exaggerated reflexes and photophobia. Vasomotor disturbances are noted—alternating redness and pallor of the face and the meningitic line. The pulse, rapid at the onset, becomes slow, and when death is near becomes small, frequent, and irregular. Such is the *ensemble* of the alarming symptoms observed in bacterial cerebrospinal meningitis and which are likewise observed in meningitides of otic origin which, as Korner and Huguenin point out, are merely incomplete meningitides, arrested in their progress toward suppuration.

In most cases of meningeal reaction arising, for example, in aseptic puriform pleurisy, secondary syphilis, etc., the disease presents an insidious onset with headache and asthenia. Then suddenly the temperature goes up, followed by either a frontal or an occipital headache, but without a distinct localization. The meninges may react although they may not be directly attacked by the infectious agent, and Rist has shown that bacteria confined to a limited area in the body may determine a diffuse inflammation of the meninges although their location may be far distant from the cerebrospinal system. A meningocortical syndrome may be observed when fluid is injected into the spinal canal and Ravaut and Aubourg have shown experimentally that the intraspinal injection of a non-isotonic liquid may produce congestion of the meninges, the want of isotonia of the solution explaining perhaps the morbid phenomena presented.

Not one of the symptoms of bacterial cerebrospinal meningitis is therefore characteristic of this affection; with the exception of meningeal reactions there is not a single one that may not be encountered during the evolution of this latter meningeal state. In some cases it is the causal disease that attracts all the attention of the physician and the meningeal reaction simply complicates these distinctly characteristic infections. Syphilitic affections of the nervous system, the toxic agents of chemical nature—as in renal insufficiency or puerperal eclampsia or poisons introduced by injections into the spinal canal, may determine irritative or exudative lesions of the meninges giving rise to a cloudy, puriform, and aseptic cerebrospinal fluid. The meningocortical syndrome can therefore complicate distinctly characterized infections, although not always easy of recognition, and the clas-

sic phases observed in the other meningitides must not be expected to be found in these meningeal states. Their onset may be sudden or prolonged, while the meningeal tripod—headache, vomiting, constipation—will be rarely complete. Fever may be absent and frequently is irregular. The pulse is normal or only slightly increased during the entire evolution of the process. The delirium is not so violent as it can be in suppurating meningitis, while pareses, and local paralyses are fleeting. Stiffness of the neck and Kernig's sign are often present, likewise ocular symptoms.

The differential diagnosis between meningeal reactions and septic meningitis is consequently embarrassing and it is only by lumbar puncture that a diagnosis can be made with any degree of certainty. There is not a single clinical symptom belonging to true or pseudomeningitis which can be regarded as pathognomonic.

IDEALISM IN MEDICINE.

POSSIBLY there is more idealism among medical men than among the members of any of the so-called learned professions. The drawback is that in hitching one's chariot to a star one is not only apt to fall but to fail in life from the material standpoint. However, the true idealist is not discouraged by a knowledge of this fact, as he does not hanker after the fleshpots of Egypt, but is content to strive to reach the heights he may never attain. The roll of doctor contains the names of many men of this stamp. John Hunter belonged to this category, for while he achieved success, to the end of his life he was attempting to gain the summit. The idealist is not satisfied with success in a single branch of endeavor; indeed if he were satisfied he would not be an idealist. In the annual oration of the Hunterian Society on February 16, Dr. H. H. Bashford took as his text the ideal element in medicine illustrated by the life of John Hunter. He began by regretting that at the present time so little is heard of medicine as an art, because it is chiefly as it is regarded from this standpoint that its ideal element becomes manifest. Bashford went on to say that, although art has never yet perhaps been successfully defined, it is in any case a giving out, a yielding up, an expression, the concrete acknowledgment in some shape or other, of the divine privilege of consciousness. The true artist, whether he would or not, is thus always an altruist; and, although he is ever in pursuit of an ideal he may never attain, he is yet the happiest man alive, whether renowned or obscure.

The definition of art places many medical men in the list of idealists, for what profession is more altruistic than that of medicine? Bashford then proceeded to compare, taking Hunter as an example, the kind of regard in which the art of medicine and its practitioners are held in these days and were held in the time when the

great investigator and surgeon lived. The condition of medicine and surgery in those days was almost stagnant and it is pointed out that in Hunter's own country, Scotland, at the time of his birth, all that was required before qualification, before the conferring, that is to say, of the title of surgeon apothecary, was a three years' apprenticeship to some surgeon apothecary already in practice, who was himself in too many cases a deeply ignorant person. The candidate had then to appear before the College of Barbers and Surgeons, the barbers, by the way, had recently dropped out, when he would be required to dissect a part, write a thesis, and make up a prescription. There were exceptions, of course, to this state of ignorance. Harvey's researches were known and accepted, the thermometer had been discovered but was little used, the early microscope had revealed the presence of red corpuscles in the blood, the tourniquet had been invented, while inoculation against smallpox had just been introduced into Europe by Lady Mary Montagu, that she meteor as Horace Walpole described her, although, as Bashford remarks, it was being strongly opposed by the clergy as an interference with the divine prerogative. However, in spite of these discoveries and inventions, which were employed by only a few men, "the mind of contemporary medicine was still largely clouded by the medieval legacy of formulating in advance some all-embracing hypothesis with which facts and treatment had to be made to square."

Referring to the growth of medical power, the speaker said that even with the picture before us of the position of medicine in the year of Hunter's birth, it is perhaps doubtful whether we any of us have quite realized how great that stride has been. The doctor is needed everywhere and wields almost unlimited power, "not only in the sick room and the hospital, but in the every-day life of the school and the factory, in the building of houses and the planning of towns, the community of to-day demands his presence." As for the teaching and training of the embryo medical man, Bashford rightly warned against the dangers of an expensive curriculum and of medicine becoming the preserve of a particular social class. Up to the present time its gates have stood more widely open, perhaps, than those of any of the so-called learned professions. But stress is laid on the point that, with the increased length and necessarily increased cost of medical education, there would seem to be a danger that in future only the better endowed will be able to undertake it. This statement applies more forcibly to Great Britain than to any other country. Idealism, which is the fuel that feeds and keeps the flame burning brightly, will be kept ablaze by the example of such men as Hunter. Medicine, to continue in its path toward an idealistic goal, must be taught in a more human way. The student should know something of the life work of the pioneers of and the great men in medicine and

surgery. The art of medicine should not be dry as dust, but be invested with a personal interest. Some at least of the romance of medicine should be imparted to those who are intending to make of it a career, in order that they may learn how difficulties have been overcome and success and fame have been attained by the great surgeons and physicians of the past. In short, and in these times in particular, when the aim of most seems to be to outvie their neighbors in extravagance, idealism, as exhibited by John Hunter and a host of bygone medical worthies, should be cultivated by the rising generation of medical men, the idealism, indeed, now being practised by another remarkable Scotchman, Sir James Mackenzie.

PRIMARY GANGRENE OF THE PREPUCE AND SULCUS PENIS.

GANGRENE in the balanopreputial fold remains the same mysterious affection, despite all advances of science. We at once exclude the secondary sloughing seen in chancre or chancroid with phimosis, although as a matter of fact there is little if any difference between the primary and secondary condition. In a certain number of cases primary gangrene may follow coitus or simple traumatism, but no distinction can be made between cases which originate in the sulcus and others which may first appear on the shaft of the penis and scrotum—authors often speak of penoscrotal gangrene to denote that one malady may originate in the entire genital area. In some of these cases the condition corresponds to gangrenous erysipelas, but in the majority the latter affection does not figure at all. Milian and two others report a case of primary gangrene of the balanopreputial fold which appeared a few days after coitus (*Bulletin de la Société Française de Dermatologie et de Syphiligraphie*, 1920, no. 8). Persistent efforts were made to find Ducrey's bacillus and autoinoculation was practised but chancroid could be definitely excluded. Blood cultures were negative (the patient had considerable fever). There was inguinal adenopathy. Although a spirocheto-bacillary symbiosis was found in the pus, the author says nothing of a Vincent infection. Syphilis in any stage was apparently excluded, although the authors do not discuss this possibility. The fusio-spirillary association was also accompanied by streptococci. The case ended in recovery with hardly a trace but the symptoms were for the time somewhat menacing. In the foudroyant type of this affection death may rapidly come about from sepsis, while in other patients there may be extensive local mutilation. Admission of air is the indication for treatment, since we are dealing with an anaerobiosis.

THE OCULAR SYMPTOMS AND CEREBRAL LOCALIZATIONS OF ENCEPHALITIS LETHARGICA.

MORE or less marked ocular disturbances are almost constantly met with in encephalitis lethargica, and to read the reported cases it would seem as if these ocular manifestations were very varied and that the clinical symptoms are rarely the same in any two

cases. But they nevertheless can be classified and grouped into recognizable forms. Paralyzes and nothing else represent the ocular symptoms of encephalitis lethargica, but these paralyzes are of divers kinds. At times they are partial, involving only such or such a branch of the common oculomotor, while at others the entire nerve is involved. Finally, they may affect the form of paralyzes of associated movements. These associated paralyzes are frequently hardly outlined, making themselves evident by an atypical and variable diplopia, and also by bilateral nystagmiform jerks, which, according to Sauvinau, are characteristic of the existence of a mild degree of associated paralysis. These different clinical forms would lead us to suppose that equally different anatomical localizations exist. The simple paralyzes—partial or total—of the oculomotor nerves have a nuclear origin, but the associated paralyzes would seem to point to a lesion situated higher up than the mesencephalic nuclei. Now, in reality, at autopsy precisely the same lesions are found that were formerly described by Wernicke in cases of hemorrhagic polioencephalitis and which Sauvinau, in 1892, used for the basis of his theory of the supranuclear centers. The existence of these centers of coordination explains the paralyzes of associated movements, whose clinical picture had been previously described by Parinaud with, however, the exception of the nystagmus to which they give rise. At the present time this theory is quite generally accepted, but the exact localization of the supranuclear centers still remains to be discovered. It would consequently be interesting, when examining subjects dead from encephalitis lethargica after having presented associated paralysis during life, to search carefully for the exact site of the lesions, because it might lead to the anatomical discovery of the supranuclear centers.

News of the Week.

Philosophical Society Awards Honors.—Among those to whom the American Philosophical Society awarded the John Scott medal for scientific work of high order, at its general meeting in Philadelphia, April 23, were Dr. Edward Calvin Kendall of Rochester, Minn., for his feat in having isolated the iodine compound in the thyroid and the establishment of the chemical identity of thyroxin, and Dr. Hideyo Noguchi, of the Rockefeller Institute for Medical Research, for having succeeded in isolating the germ of yellow fever and producing a serum to combat its action. It was announced that another John Scott medal would be struck next month and presented to Madame Marie Curie during her visit to this country.

Insane Ex-soldiers Increasing.—According to an informal report submitted by Colonel Cornelius W. Wickersham, Chairman of the American Legion's investigating committee for disabled soldiers, insane ex-service men are increasing in New York State at the rate of between two and three hundred a month. The Federal Government has provided only 177 beds for the mentally deficient in hospitals in this State. The report points out that there is no way to determine the exact number of insane veterans in New York City without hospitalization,

but the committee believes it is extremely large because so many parents and guardians of insane men have appeared before the committee urging that something be done to hasten relief. A similar situation is reported to exist as regards tuberculosis. A recent Federal report shows that up to April 1, 1921, 716,682 physical examinations for disability in ex-soldiers have been made. The number of men given some hospital treatment to April 1, is 118,636; the number of men in hospital on this date was 20,045. The number of men in Government hospitals deemed unsuitable is estimated at 10,000. New hospital accommodations are urgently needed for 19,400 men.

Bubonic Plague in Egypt.—A cablegram from Alexandria, Egypt, under date of April 21, reports that bubonic plague has broken out in that city, and an average of thirty-five cases are being reported daily. A quarantine is being imposed, and vessels have been leaving the port in order to avoid being held.

Suicides in Budapest.—A communication from Captain Pedro, chief of the American Red Cross at Budapest, states that the famine there is increasing. He declares that during March alone 1200 suicides in Budapest were caused by the famine and that similar reports are arriving from lesser Hungarian towns.

Favor Advertising to Warn Public Against Quacks.—The Franco-Anglo-American League against Cancer has put itself on record as favoring the publication of advertisements by reputable medical organizations to counteract the exploiting of quack remedies for cancer. The suggestion is that advertisements signed by the Pasteur Institute, the Academy of Medicine, or the Franco-Anglo-American League against Cancer be published in the non-medical press, warning the public against quack remedies, giving details of early symptoms of cancer, and information as to where to apply for treatment. Many physicians present agreed that a similar system might well be applied to other common diseases.

Cure of Encephalitis Lethargica Reported.—According to a cablegram from Paris, C. Levaditi and H. Larvier of the Pasteur Institute announce cures of lethargic encephalitis by means of a new serum. The description of the serum has not yet been given out.

Chicago's Allowance of Medicinal Alcohol.—According to an announcement made by Ralph W. Stone, prohibition director for Illinois, each of the two thousand druggists of Chicago may withdraw two hundred gallons of whiskey and two hundred gallons of wine every three months. The commissioner of internal revenue has announced that this quantity could be increased if the druggists could show that they really needed more liquor to supply the demand. At this rate Chicago would be using 3,200,000 gallons of wine and whiskey a year for her 3,000,000 inhabitants.

Annual Registration in Utah.—Under Senate Bill No. 35, creating the department of registration, the members of all professions who heretofore have been licensed are required annually to renew their licenses. The date set for registration in Utah is May 1, and the annual fee to be paid is \$5.

Medical College Retains the Term "Homeo-

pathic."—A proposal to drop the word "homeopathic" from the name of the New York Homeopathic Medical College met with unanimous disapproval at a recent meeting of the board of trustees of that institution.

Fund to Provide Glasses for School Children.—The Junior Red Cross of New York City, at the request of the New York City Principals' Association, has established a \$5,000 loan fund from which parents may borrow the amount needed for the purchase of glasses for their children. Over 200 children have already used the fund, paying back in instalments the total sum borrowed.

Cooperation Between Nursing Forces.—A plan of cooperation for constructive field work has been agreed upon by the directors of the public health nursing of the State Department of Health and the Atlantic Division of the American Red Cross, so that the former may have the advantage of the assistance of local field nurses in the employ of the Red Cross whenever necessary and possible, and may also be kept informed of the extent and character of the work of local Red Cross public health nurses.

Work of Babies Welfare Federation.—The Babies' Welfare Federation of New York City has recently made public its annual report for 1920, which shows that through the agency of the various organizations belonging to the federation more than 15,000 children of needy families have been cared for during the year. Public health nurses have visited 12,641 mothers to make sure that new born infants are receiving proper treatment and that the mothers are taking advantage of the facilities offered by the Baby Health Stations of the city. Hospital treatment, as well as convalescent and fresh air care, have been provided for a large number of other children, while more than 2,000 whose mothers are obliged to go out to work have been placed by the federation in homes certified by the city.

Hospital Changes Hands.—Dr. J. J. Moorhead and Dr. Irving S. Haynes have acquired possession of the Washington Square Hospital, of which Dr. Carlo Savini was formerly the head.

Dr. Ales Hrdlicka of the American University, Washington, D. C., has received a diploma from the University of Prague conferring upon him the degree of Doctor of Science.

Dr. Peter L. McKallagat has been appointed city physician of Lawrence, Mass., to succeed Dr. W. J. Sullivan, who recently resigned.

Dr. John H. Jamar of Elkton, Md., was tendered a complimentary dinner by the Cecil County Medical Society on the evening of April 6, on which occasion he was presented with a gold-headed cane.

"Modern Medicine" Changes Its Name.—Announcement is made that, beginning with the May issue, the name of *Modern Medicine* will be changed to *The Nation's Health*. This change is made so that the title will be more clearly descriptive of the present scope of the magazine.

Opposed to an Increased Tariff on Surgical Instruments.—At a meeting of the Hospital Conference of New York City held April 13, the following resolution was adopted: *Whereas*, A bill has been presented to Congress to increase the tariff on surgical instruments; and the Hospital Conference of the City of New York, representing forty of our

leading hospitals, is opposed to this increase, because of the additional burden it will entail in our charitable work. Therefore be it *Resolved*, That the Conference would respectfully call to the attention of Congress the injustice that would be wrought upon charitable institutions by an increase in the tariff on surgical instruments.

Goucher College Aids Radium Fund.—A mass meeting was held in Goucher College "further to acquaint the people of Baltimore with the importance of Madame Marie Curie's work for pure and applied science," and to enlist aid in raising the fund of \$100,000 with which to purchase a gram of radium for Madame Curie, was held on April 11. Dr. Howard Kelly and Dr. Florence Sabin of Johns Hopkins made addresses.

Physician Acquitted.—Dr. William B. Wilkinson of New Brighton, Staten Island, N. Y., who was accused of having caused the death of Mrs. Ethel M. Heier by an illegal operation, has been acquitted of the charge of manslaughter by the Supreme Court at St. George, S. I., which found that the operation was necessary to save her life.

Medical Society Elections.—THE THIRD DISTRICT MEDICAL SOCIETY, at its meeting in New Albany, Ind., April 8, 1921, elected the following officers for the ensuing year: *President*, Dr. J. L. Mitchell, Salem; *Secretary and Treasurer*, Dr. Claude Paynter, Salem.

THE NEW JERSEY SECTION OF THE AMERICAN COLLEGE OF SURGEONS, at its first annual meeting, held in Newark, April 11 and 12, 1921, elected the following officers for the ensuing year: *President*, Dr. Edward J. Ill, Newark, N. J.; *Secretary*, Dr. Carl E. Sutphen; *Counselor*, Dr. James J. Brown, Montclair.

THE IBERIA PARISH (LOUISIANA) MEDICAL SOCIETY, at a meeting held in Iberia, April 14, elected the following officers: *President*, Dr. George J. Sabatier; *Secretary and Treasurer*, Dr. Walter F. Carstens.

Obituary Notes.—Dr. NORMAN RICHARDS JENNER of Washington died suddenly of heart disease at his home, on April 16, at the age of fifty-nine years. He was graduated from the Georgetown School of Medicine in 1891.

Dr. WILLIAM H. RICE of Atlanta, Ga., a graduate of the Southern Medical College, Atlanta, Ga., in 1889, and for forty years a practitioner of that city, died suddenly of apoplexy on April 2.

Dr. E. K. MAY, a graduate of Vanderbilt University and of the University of Chicago, died at his home in Maytown, Ky., on April 2, at the age of forty-eight years.

Dr. NEWTON B. WACHHORST, for thirty-five years a practitioner of San Francisco, Cal., died there suddenly, on March 28.

Dr. AUSTIN I. HARVEY of Bangor, Me., died suddenly from angina pectoris, on April 9, at the age of sixty-eight years. He was a graduate of the Hahnemann Medical College, Philadelphia, in 1878, and was a member of the State Board of Registration since 1895.

Dr. FREDERICH KOLBENHEYER of St. Louis, Mo., died at the home of a relative in Omaha, Neb., about April 6, at the age of seventy-eight years. He was a graduate of the Kaiserliche Königlich Universität, Vienna, in 1868.

Correspondence.

TREATMENT OF FOOT ILLS.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—I was surprised to see in a recent number of the MEDICAL RECORD an editorial endorsing the licensing of the self-styled "Podiatrists," and advocating the giving of courses in medical schools to otherwise unqualified students who wished to gain a living by practising such a specialty. The excuse, or reason, given for such licensing and establishment was that the average doctor was unqualified to treat weak feet, anterior metatarsalgia, painful heels, and bunions—the more common, not to say vulgar, group of ailments to which the foot is subject. This premise is true, but the suggestion based upon it is an archaism. It is a concession to a prejudice, and to a prejudice founded primarily upon snobbery. Its adoption would open the field of medicine to further encroachments on the part of the semi-educated, such as the optometrist, the chiropodist, the chiropractor, and the osteopath.

Granted that the average physician or surgeon does not know how to treat the various disabilities of the foot, why is this so? First, because he never received any proper instruction upon the subject in the medical school. Good courses in orthopedic surgery are even now rare, and in the few good ones the mechanism and disabilities of the foot do not receive a fair share of attention. It is an almost irresistible temptation for the practitioner to disguise his ignorance by making light of the seriousness of these conditions, and sending his patients to the chiropodist or brace-maker, in the meantime soothing his own conscience by the more or less subconscious reflection that treating feet, anyway, is not quite genteel, and that one who treats feet is subtly tainted with the odor of blacksmithing, farriery, or veterinarianism.

The influence of social tradition upon the practice of medicine and surgery would make an interesting subject for study. It is not so very long since surgeons and barbers were members of the same social stratum. Indeed, in England surgeons were originally subordinate members of the Guild of Barbers, and pulling themselves up from that level, more or less by their own bootstraps, has been a long, painful, and exasperating process. The modern orthopedic surgeon is continually annoyed by the popular confusion of orthopedics and chiropody. Up to recent times considerable social disability has been attached to the practitioners of various specialties. Dental surgeons are just now emerging from it. However, now that proctologists and genitourinary specialists are no longer apologetic for interest in their peculiar fields, I see no reason why the average practitioner should not apply himself to coping even with the vagaries of the lowly foot, instead of advocating the licensing of a new order of the semi-educated to do it for him.

The truth of the matter is that feet have never been accorded their due measure of consideration. The female foot is generally regarded as being a neat finish to a lady rather than as a legitimate

aid to her locomotion. The male variety functioned as a comic adjunct to a policeman, its locomotive importance having only lately sprung into prominence as a means of getting out of the draft.

From an esthetic standpoint du Maurier was the first to call attention to the deforming effect of footwear, and the baneful influence of bunions upon love's young dream. Nowadays the esthetic considerations, of course, may be summarily dismissed as of no importance, but can one disregard the effect of bad feet upon our national efficiency? Were not almost 40 per cent. of candidates for the draft rejected because of flat feet? Are not the dispositions of a large percentage of domestic servants ruined by them? How many fat men give up golf, how many women dancing, because their feet hurt? What is the influence of painful feet upon the development of obesity?

After mature consideration of these facts, would it not be well for the medical profession to educate itself in the proper mechanical use of the foot, and the causes and treatment of its common disabilities, to inculcate in the public mind the idea that the foot is primarily useful, and perhaps to alter its present conception of the foot it now regards as ornamental? Perhaps, then, in a future generation 40 per cent. of our country's defenders who spring to arms overnight will not have to limp home before sundown. Viewing feet, therefore, from the standpoint of their national importance, are they not worthy of the distinguished consideration of the present practitioners of medicine? Shall we throw 40 per cent. of our young men to the podiatrist?

ARMITAGE WHITMAN, M.D., F.A.C.S.

283 LEXINGTON AVE., NEW YORK CITY.

OUR LONDON LETTER.

(From Our Own Correspondent.)

LONDON, April 5, 1921.

Tuberculosis Conference.—The second conference of the International Union against Tuberculosis will be held in London from July 26 to 28 at the Engineering Hall, South Kensington. Sir Robert Philip, president of the International Union, will preside, and the conference will be attended by delegates from the United States and from twenty-four countries within the League of Nations. The retiring president, M. Leon Bourgeois, member of the French Senate, will deliver his valedictory address, and a discussion on the modes of diffusion of tuberculosis throughout the world will be opened by Professor Calmette of Paris. All arrangements for the conference are being made by the National Association for the Prevention of Tuberculosis, 20 Hanover Square W., the members of which will act as hosts to the International Union.

Free Nursing Scheme.—The introduction of free nursing for panel patients in Manchester is expected in the near future. Discussing the scheme with a press representative recently, Councillor Walter Davis, chairman of the Manchester Insurance Committee, said that some time ago meetings were held for the purpose of co-ordinating as far as possible, the various nursing schemes in operation in the city. He put forward

a proposal under which panel patients could have a nurse when the attending doctor deemed one necessary. The local insurance committee promised £1,000 towards the costs and the City Council voted £500. Subsequently, approved societies were recommended to vote out of their funds 3 pence per head per annum for nursing, and for the time being the scheme was held up until the final decisions of the various societies were received.

R. A. M. C. Memorial.—Important decisions have been taken in regard to the memorial which is to be erected to commemorate the officers, non-commissioned officers, and men of the Royal Army Medical Corps who were killed in action or otherwise lost their lives during the war. The amount contributed to the Memorial Fund is £19,328, but £1,566 has been ear-marked by donors for families and dependents of the fallen, and the sum will be allocated for administration to the R. A. M. C. Regular and auxiliary funds in proportion to be determined by the general committee. After consultation with representative officers and other ranks of all branches of the Corps, and with the cordial and generous consent of the Dean and Chapter, the General Committee have resolved to erect a tablet in Westminster Abbey, in a suitable position on the wall near the grave of the Unknown Warrior, and also to place in the Chapter House of the Abbey for permanent keeping, a Golden Book containing the names of all the members of the Corps whose services and sacrifices the memorial is designed to commemorate. Replicas of the tablet will be presented to Edinburgh and Dublin, to be placed in positions chosen by the city authorities. The provision of the memorial in these forms will be the first charge on the unallocated portion of the memorial fund, and the balance, probably not less than £10,000, will be devoted to the fund now being raised for the restoration of certain portions of Westminster Abbey. The gift will be recorded on the tablet to be placed in the Abbey wall, and it will not only be in keeping with the fine work and traditions of the Corps, but will gain additional significance and appropriateness from the fact that very many of the fallen, both officers and men, belonged at the outbreak of the war to the civilian side of the medical profession.

Death Rate from Phthisis and Tuberculosis.—A question was asked of the Minister of Health in the House of Commons on March 22, as to the number of deaths and the death-rate per 1000 from phthisis of all forms in Great Britain in 1920, and similar figures for the previous five years. The question was also put, whether as a measure of public economy he proposed to reduce the number of sanatoriums and beds available for the treatment of this disease. The Minister of Health replied that the total deaths during the past six years from 1915 to 1920 inclusive from all forms of tuberculosis were as follows: 54,295, 53,858, 55,934, 55,073, 46,312, 42,545. The death rates per 100,000 of the population for the same years were as follows: 151.5, 152.9, 162.4, 169.4, 125.8, 112.8. As the Minister had stated already, the figures for the last two years were the most encouraging since the inception of the national

scheme for the treatment of tuberculosis. The number of sanatoriums and beds available for coping with the disease was not to be reduced.

French Birth Rate.—According to the correspondent of the Daily Telegraph in Paris, the French Senate has been occupied recently with the problem of the reduced birth-rate which has troubled ministers and the medical profession for many years, but which continues to become more grave. The debate, which arose out of discussion of health ministry credits, was opened by M. Fernand Merlin, who emphasized the alarming drop in the number of births. From 1914 to 1920, he stated, there were recorded 2,779,583 against 4,232,705 deaths, exclusive, of course, of military losses, which were over a million men. There had also been nearly 70,000 soldiers incapacitated by tuberculosis. During this period the excess of women over men had risen to 2,500,000. That illustrated the peril incurred by the nation. Before the war infantile mortality had risen to 15 per cent, and since the war the population of the country areas had diminished in disquieting proportions. The problem of repopulation, he declared, was as important to France as that of finance. The two questions were inseparable. He asked for a more vigorous effort in combating tuberculosis and other maladies and greater aid to mothers and children. M. Leredu, the Minister of Health, said they must make the utmost efforts so that the French race should be defended against social plagues. The people of France must understand that unwillingness to rear families was a crime against the country. They would be the vanquished of tomorrow if their race was not equal in number to that of other races. It was the feeling of many Senators that the problem was not to be settled by an increase of the credits to the Health Ministry. Canon Collin, the Senator for the Moselle, believed in the benefits of creating a sympathetic public sentiment. "Religion," he said, "which tells women their duty is the universal remedy." All the requests for increased credits to the subvention of maternal and child-aid institutions were rejected.

Venereal Disease Patients.—At the annual meeting of Governors of the London Lock Hospital and Rescue Home, a week ago, the secretary stated in his annual report that during the year 648 inpatients had been treated at the female hospital, and 640 in-patients at the male hospital. No fewer than 99,689 outpatients had been treated, over 87,000 of these being males.

Obituary.—Dr. ROBERT MURRAY LESLIE of London died on March 29. Dr. Leslie was 54 years of age and a well-known specialist in diseases of the chest. He was senior physician to the Prince of Wales's General Hospital and consulting physician to the Royal Hospital for Diseases of the Chest, City Road. Dr. Leslie was a remarkably able writer. He was a man of charming disposition and manners, kindly and courteous to all but absolutely unassuming.

Dr. RUTHERFORD JOHN PYE SMITH, Emeritus Professor of Surgery in the University of Sheffield and consulting surgeon to the Sheffield Royal Hospital, has just died. Although of old Sheffield stock he was born in London in 1848, became P.

R. C. S. in 1875, and went to Sheffield in 1876. Like the older school of surgeons, in addition to his operative work and lecturing, he carried on a large general practice. He was old-fashioned in his ways, motorcars, typewriters, and shorthand clerks were anathema maranatha to him. He wrote all his own letters and he was a voluminous letter writer. He prepared all the patients for operation and put on the dressings afterwards. Everything from beginning to end was done by himself. When the University of Sheffield was constituted, Pye-Smith was elected the first professor of surgery.

Dr. ALEXANDER WINTER BLYTH, public analyst for the County of Devon and the Borough of Marylebone, died suddenly on March 30 in the 76th year. Born at Woolwich, the son of a medical man, Dr. Blyth was educated at King's College, London, and qualified as a medical practitioner in 1870. He was a past president of the Incorporated Society of Medical Officers of Health and Registrar of the Sanitary Institute. Dr. Blyth was the author of a number of works on public health, foods, diet and poisons and their detection.

LETTER FROM GENEVA.

GENEVA, March 15, 1921.

Epidemic Hiccough.—As some cases of epidemic singultus have been observed in the Jura district of Switzerland, the Health Department of Geneva has issued a circular to physicians requesting them to report any cases coming under observation. Although as yet there is no general epidemic of the affection a close watch should be maintained in order to study it from the onset should one develop. This form of singultus belongs in reality to the myoclonic syndrome of encephalitis lethargica; it is met with associated with other symptoms of the infection, singly or as a larvate form of encephalitis, as has been observed at Vienna, Berlin, Paris, and Geneva. The Health Department considers it quite essential to follow this affection very closely in order to ascertain what may be its etiological relations to encephalitis lethargica.

In France a recrudescence of this peculiar affection was noticed at the end of 1919 and is still present. In January of last year Dufour reported three cases of singultus with pyrexia. During an epidemic of encephalitis lethargica at Versailles, Bérard made the same remark and it would now appear that this infectious endemic singultus is unquestionably related to encephalitis, the clinical manifestations of which are at present quite numerous. Sicard and Paray had occasion recently to observe twenty-seven cases of the disease, thirteen being among the employees of the Omnibus Company of Paris. They state that the disease is often ushered in by lassitude, epigastric tension, and mild pyrexia, but they also found that in numerous cases the attack suddenly develops in the midst of flourishing health. The diaphragmatic jerks appear without warning while the patient is at his work. The clonias of the diaphragm—the singultus being in reality a myoclonia like that met with in a certain number of cases of encephalitis—and spasms of the

glottis alternate with a rhythmical paroxysm lasting for a half hour to an hour, with an average cadence of six to eight per minute. The interval between the paroxysms varies, but seems to be about two hours, sometimes more, sometimes less, but the night is usually calm. The entire cycle is from two to three days, after which the patient recovers as suddenly as he was suddenly taken ill. Netter, however, has seen some cases that lasted six or more days. Reappearance or relapses are certainly uncommon.

The temperature is usually about 99.5° to 100° F., but in some few cases it has reached 102°. The pulse remains normal and occasionally it has been slow. The blood-pressure seems to be slightly lowered during the paroxysms; the cerebrospinal fluid is normal. No ocular disturbances have so far been reported and the same applies to the reflexes, and although the psychic state is quite frequently one of distress, no disturbance of an oniric nature has been noted.

Epidemic singultus has a curious preference for males, but respects no age, although the maximum number of cases so far reported were in subjects in the neighborhood of forty, so that it might be regarded as a trifling episode of encephalitis which has an individual autonomous evolution and in itself constitutes the entire disease.

The end of epidemic singultus is usually regular insofar as a cure results, but it should be pointed out that Netter is of the opinion that the possibility of the development of more serious symptoms having the same etiology cannot be excluded, so that the prognosis should be made with some reserve. As to treatment, the usual anesthetics and antispasmodics do not appear to be of any value and morphine and its derivatives especially give no results. In some cases rhythmical tractions of the tongue, epigastric or thoracic compression over the insertion of the diaphragm, distention of the esophagus by means of a thick, hard mass of food, or an ice bag over the cervical region appear to have inhibited the paroxysms to a certain extent. All things considered, however, the treatment still remains to be discovered.

The Venereal Question.—The venereal inquisitorial investigation here seems to be buzzing in the bonnets of uplifters of all countries. It is now busy in Switzerland. The investigation recently undertaken by the Swiss Association for Combating Venereal Diseases, the Swiss Medical Commission, and the Federal Service of Public Hygiene has been approved of by most physicians, but has also met with some criticism. The trouble has arisen from the fact that the blanks sent to all the profession require the initials of the patient to be given and this the Medical Society of Geneva flatly refused to do. The indication of the patient's identity is too evident, especially when he or she resides in a small town or village. The venereal disease blanks, in the case of gonorrhea in women, did not put the question as to whether or not the gonococcus was present. This omission was purposely made in order to avoid giving the physician too much trouble, but in the future it will be asked whether the patient is gonococcus positive or negative.

The text of the blank is not clear as regards complications of gonorrhea, but by the term "complications" is meant all genital and extra-genital processes, such as epididymitis, prostatitis, cystitis, arthritis, affections of the adnexa, etc. By the term "latent syphilis" the authors of the venereal disease blank define it as "syphilis without symptoms with a positive Wassermann." It is true that latent syphilis exists with a negative Wassermann, but in these circumstances the diagnosis can no longer be a precise one and at the best can mostly be presumed and can be confirmed only by the ultimate course of events. However, when the physician is persuaded that, regardless of the absence of clinical manifestations with a negative Wassermann, the patient is not cured he should mention the case as latent syphilis with a negative Wassermann.

Variability in Biology.—The monthly lecture at the Geneva Medical Society in February was delivered by Dr. de Montet of Vevey, his subject being: "Variability in Biology and the Means for Methodically Characterizing It." The lecturer stated that the need of a method adequate for the variability of data obtained is the reason for the real difficulties met with in practical experience. Life is an indecomposable process and the living complexity cannot be broken without loss of its distinctive character. By decomposing it we come down to the physical and chemical processes, such as the synthesis of urea, albuminoids, etc., and the more the organic phenomena are dissociated the more the essential escapes us, namely, life. By substituting the precise notion of interdependence for the obscure idea of complexity, we suppose in principle that every manifestation—regardless of its own character and the particular relations that characterize it—depends upon all that exists at the same time that it does, and upon everything that has preceded it. Such is the character of vital manifestation. Example: (a) coexisting influence, such as climate, epidemics, feeding, social conditions, etc.; (b) preceding influence, such as heredity, physical constitution, education, etc. The influence of these factors should not be admitted occasionally, but always in principle. Interdependence of the entire organism is distinctly manifest; thus the study of the internal secretions reveals such complex linking together that the immediate influence of one organ over another can no longer be admitted and the relations between organs are more and more regarded as chemical correlations.

Psychology shows how much our way of observing varies according to what we want to find, that is to say, that it depends upon our hypotheses. Psychology should make us attentive of the necessity of freeing ourselves from our common prejudices and without cessation to revise our principles by comparing them with facts observed. It will reveal the insufficiency of a pure empiricism which needs no principles. The present day development of international institutes for the study of the same problems is an indication of progress upon the condition, however, that they are perfected from the viewpoint of the elaboration of many data acquired. The speaker did not believe that the adequate solution resides in the

application of the laws of Quetelet, Gauss, and Pearson, such as they are ordinarily applied. Although the method of statistics has fallen into discredit it is because it has been placed at the service of uniformity without taking interdependence into consideration. It too often crystallizes into percentages those relationships which do not bear such mechanical interpretation.

Retroperitoneal Pseudomyxoma.—At the meeting of the Geneva Medical Society on February 2 Professors Kummer and Askanazy reported a case of retroperitoneal pseudomyxoma arising from an appendix formerly the seat of appendicitis in a patient sixty years of age. It is noteworthy that this is the first known instance of a *retroperitoneal* pseudomyxoma.

Typhus.—The latest data relative to exanthematic typhus received by the Swiss Federal Health department are that from June to November, 1920, there were about four million cases in Russia, including Ukraine and Siberia. In Germany there were 255 cases from November 21, 1920, to January 8, 1921. A few cases were reported from Hungary (29) and Czechoslovakia (126 cases) from October to December 5, 1920.

LETTER FROM BELGIUM.

(From Our Own Correspondent.)

LIEGE, March 31, 1921.

Sixth French Language Congress of Legal Medicine.—Returning to the prewar custom, the next French Language Congress of Legal Medicine will hold a double meeting this year in Brussels and Liège. The sessions of the first two days (May 23 and 24) will be held at the Palais des Académies, Brussels, and will be under the presidency of Professor Stokvis. Discussions will be opened by M. Holvoet, on "The Code and Abnormals"; by Professor Ley of Brussels, on "Prison Psychiatry"; and by Dr. De Laet, on "The Spectroscopic Identification of Alkaloids." At Liège there will be discussions by Professor Stokvis of Liège and M. Lerlercq of Lille on "Mechanical Asphyxia," and by Professor Delrez on "Traumatic Shock."

Rectal Incision for Appendical Pelvic Abscess.—In a paper recently read before the Belgian Surgical Society Dr. Mayer of Brussels emphasized the advantages which this treatment offered in certain cases of pelvic suppuration. The operation was advocated by Byford and Gerster in 1887 and 1890 in articles published in those years in the *New York Medical Journal*. Dr. Mayer employs this route for drainage, the general indications for which were formulated by Routier in the *Bulletin Médical* in 1912, in cases of grave complications of appendicitis in which all other forms of treatment are contra-indicated. The technique is very simple—longitudinal incision along the anterior wall of the rectum at the site of fluctuation; drainage through a large rubber tube after copious irrigation with 0.04 per cent. solution of potassium permanganate. The results of this operation are almost always excellent, and the author reported two very serious cases, recently under his care, in which the outcome was most successful.

Otic and Cerebral Troubles Following Concussion.—At a meeting of the Royal Society of Med-

jical and Natural Sciences on March 7 Dr. Mayer of Brussels reported the case of an English officer who, just before the armistice, had suffered a rupture of the drum membrane caused by the explosion of a shell near his right ear. There was immediate deafness followed by symptoms of labyrinthine commotion (tinnitus, vomiting, vertigo), very violent headache, and, seven months later, epileptiform attacks. These attacks recurred some ten times a day. The pulse was slow (52 a minute). There was suppurative inflammation of the middle ear, and the mastoid was tender on pressure. With the assistance of Dr. Merckx the author made a petromastoid évidement, removing the carious ossicles and fungous masses in the tympanum, followed by temporal trephining. The brain, compressed by an encysted serous exudate, did not pulsate; but pulsation returned the following day after evacuation of the liquid, and a speedy cure took place. At the present time, six months after the operation, the patient is in excellent condition; the headache gradually disappeared within a few days following the operation, and the epileptiform attacks never recurred. The author found a satisfactory explanation of the pathogenesis of the ruptured drum membrane of the labyrinthine commotion, and of the tympanic suppuration in the violent atmospheric displacement caused by the explosion of the shell; but the pathogenesis of the endocranial lesions seemed to him somewhat obscure.

3. Report on Recent Progress in Dermatology. John T. Bowen.

2. Basal Metabolism as an Index of Treatment in Diseases of the Thyroid.—Frank E. Lahey and Sara Murray Jordan trace briefly the history of the development of the study of metabolism, and present nine charts illustrating, respectively, the rate of basal metabolism; the calculation of percentage variation from normal, based on observation shown in the preceding; variations in estimated rate of basal metabolism by comparison with Harris and Benedict and with Dubois normals (ten cases); pre- and postoperative basal metabolism estimation in a few cases of secondary hyperthyroidism; progressive drop as a result of a single pole ligation; metabolic rate during course of surgical treatment in ten cases of primary hyperthyroidism; two cases in which, after ligation, clinical improvement and gain in weight occurred without proportionate drop in metabolism; effect upon basal metabolism rate of injection of eight minims of epinephrin (1-1000 sol.); average rate of basal metabolism in secondary and in primary hyperthyroidism. From these observations it is concluded that in a clinic for diseases of the thyroid a test of the rate of basal metabolism is an invaluable factor in the data necessary for diagnosis, that it aids greatly in prognosis, and that it probably has its greatest value as an index of the results of treatment in any given case.

3. Acute Inversion of the Uterus.—James L. Huntington refers, in this contribution, to acute puerperal inversion of the uterus and not to the condition of inversion where a tumor, by its weight, has gradually caused the uterus to turn inside out, or where violent intraabdominal pressure has brought about the same condition, for under these circumstances the condition is essentially chronic, and the feature of hemorrhage is lacking. From his review of the subject, and from the study of a case in point, the following conclusions are drawn: 1. Acute inversion of the uterus, postpartum, can occur spontaneously. 2. Insertion of the placenta in or near the fundus of the uterus seems the most probable etiological factor. 3. Realizing the possibility of encountering the fundus weakened by being the placental site, great care should be exercised in expressing the placenta by pressure from above. 4. Shock, whether or not accompanied by postpartum bleeding, should demand immediate vaginal examination, unless the typical spherical fundus can be plainly felt through the abdominal wall. 5. Where the diagnosis is made too late for manual reposition from below, immediate laparotomy and reposition by traction with direct transfusion, offers the best chance for a successful outcome.

5. Diagnosis and Significance of Tracheobronchial Adenopathy.—Ray M. Balyeat, at the Oklahoma City Tuberculosis Dispensary, studied the chests of 449 children under sixteen years of age. Believing that the degree of infection is a large factor in determining whether or not a child will develop active tuberculosis some time in life, he tried to determine the importance of certain physical signs and roentgen ray findings as indicators of the degree of the infection. Special attention was given to the significance of the D'Espine sign as an indicator of tracheobronchial adenopathy and the appearance of the hilum shadows in the roentgenogram as a means of differentiating tuberculous from non-tuberculous glands. (D'Espine claims that in young children the tracheal voice normally ceases at the level of the seventh cervical spine. In those cases in which the lymph nodes are enlarged at the root of the lungs, the tracheal voice will be heard over the upper thoracic spine when the patient whispers "thirty-three.")

From his study of the 449 cases the writer makes the following deductions: 1. A positive D'Espine sign is indicative of enlarged glands at the root of the lungs. 2. Enlarged tracheobronchial glands may be due to any one of several causes, the chief of which is an infection by the tubercle bacillus. 3. If tonsillitis, whooping cough, or measles causes enlarged tracheobronchial glands, they are usually not of sufficient size or density to give a positive D'Espine sign. 4.

Chronic bronchitis will produce enlarged tracheobronchial glands which can be differentiated from a tuberculous hilum by means of the roentgenogram. 5. A positive D'Espine sign found in a poorly nourished child usually is evidence of tuberculous infection of the hilum. 6. The degree of the infection can be determined by the roentgenogram. 7. Weight below standard is very common in children with a chronic tuberculous infection. 8. A child with a massive chronic tuberculous infection is a candidate for active tuberculosis, and should be watched carefully for early signs and symptoms. 9. In chronic tuberculous infections in children, few signs can be elicited by physical examination. 10. The degree of the infection in childhood is an important factor in determining whether or not a child will develop active tuberculosis in adult life. 11. Every child should have a thorough physical examination with the idea of determining if possible whether or not there is a tuberculous infection of the chest, and if so, how heavy. 12. Those with evidence of massive infections should be taught how to live and should be instructed in the signs and symptoms of early tuberculous activity. If this were done, the number of advanced cases of pulmonary tuberculosis would be greatly reduced.

9. Nutritional Work in Public Schools.—Katherine B. Rich, in her final report of experimental work done under the supervision of the Board of Education of Chicago, states that it is entirely possible to carry on nutritional work in the public schools without rest periods or free milk, and to obtain appreciable gains in weight and height. It is also possible to place the responsibility for their gains on the children, to their great advantage and with a saving of the nutritional worker's time. It can be done without seriously interfering with studies or classes, and both mental and physical gains more than compensate for the small amount of time lost. One efficient nutritional worker can, at a minimum, teach and care for and do clerical work necessary for 400 children each week. It is not an expensive per capita proposition, handled along the lines followed in these experimental studies. The percentage of gains can be greatly increased over what have been obtained if all-time workers are employed, and if the work has the unqualified backing and support of the school authorities, thus dignifying it as being part of the regular school program. Fifty per cent. of the children that were weighed and measured were found to be below normal in height and weight for age, or in weight for height, and that would approximate the findings in other localities, in all probability.

The country-wide interest that has been aroused in the subject of undernourishment has come none too soon; but unless the interest is wisely directed it will do as much harm as good. It should, primarily and justly, be the problem of the medical profession, of the pediatrician, and particularly of the family physician. For the benefit of the coming generations it might very wisely be given great emphasis in the teaching of the pediatric departments of medical schools.

10. The Quinotoxin Myth.—Torald Sollmann examined the data on which were based the assumption that the toxic effects of quinine are due to the formation of a more toxic substance, "quinotoxin," or quincin, as it is more properly called. It has been held that this may be formed from quinine under suitable conditions, especially in the presence of free organic acids, that these conditions would arise in the stomach, and that prescriptions containing quinine and an organic acid would be dangerously incompatible. These assumptions are not justified by the facts. At most, insignificant traces of quinotoxin could be formed in the body or be present in such prescriptions, and the formation of considerable quantities would not be dangerous. It may be formed in prescriptions containing quinine and organic acids, but this would proceed very slowly, and the quincin would undergo further transformation into inactive products. Such solutions are perfectly proper if used within a few days. They should not, however, be used after prolonged standing, when they have become discolored and precipitated; but this is not because they have become toxic, but only because they have become inactive.

2. Alcohol and Syphilis as Causes of Mental Disease.—George H. Kirby bases this study on data obtained from Bellevue Hospital and thirteen New York State hospitals located in various parts of the State. The data presented regarding the past and present rates of incidence of alcoholic and syphilitic mental disorders in these hospitals would seem to justify the following conclusions: Alcoholism has declined perceptibly in the general population during recent years, the beginning of the decline antedating by some years the restrictions due to war conditions and the passage of the federal prohibition amendment. Coincident with this decline, there has occurred a remarkable fall in the number of alcoholic psychoses, the lowest figure on record having been reached in 1920. During the first period of the World War, there was a noticeable recrudescence in both alcoholism and alcoholic mental disturbances; but after the United States entered the war in 1917, there was again a sharp fall which, so far as alcoholic psychoses are concerned, has not been again interrupted. Psychoses due to syphilis reached the highest point of which we have a record in the year 1918. Since then a decline in the relative and actual number of cases has occurred which, in view of the increase of population, may be regarded as at least a hopeful sign. Whether or not the more thorough and scientific treatment of syphilis in its early stages will bring about a further reduction of neurosyphilis and syphilitic psychoses is a question to be answered in the future. From the standpoint of mental hygiene, the situation may be regarded as encouraging. A notable advance has been made in the direction of controlling one of the outstanding causes of mental disease, namely, alcoholism, and as regards a second great cause of mental disease, namely, syphilis, there are indications that education, prophylaxis and improved methods of treatment are beginning to yield some results, as yet slight, to be sure, but nevertheless sufficient to be considered a sign of progress.

3. Abruptio Placentæ.—Edgar Snowden reports a case of hemorrhage occurring from premature separation of a normally implanted placenta, more precisely termed, abruptio placentæ, which is one of the most serious conditions encountered in obstetrical practice. The term abruptio placentæ is properly applied to an accident occurring in the last three months of pregnancy, for the condition arising prior to the period of fetal viability should be considered under the various forms of abortion and miscarriage. Toxemia, trauma, nephritis, diseases of the placenta and decidua, endometritis, obstruction to the uterine circulation, have been proposed as causes, none of which, in the writer's opinion, can produce a complete symptom picture of a case of abruptio placentæ. He believes a true toxemia is undoubtedly to blame, while these other conditions are but secondary. The sources of the toxin are open to speculation; but from the pathological changes produced the evidence points to some intrauterine condition, due to the pregnancy itself, and possibly being of placental origin. The initial lesion may be the so-called "uretero-placental apoplexy." The onset of a typical case is of a sudden and violent nature, the severity of the symptoms depending on the degree of separation. The management of the case depends on whether or not labor has begun, and the degree of cervical dilatation; but under any circumstances three indications are to be met: The uterus must be emptied, the hemorrhage stopped, and the anemia combated. The best treatment is that which, with the least danger to the mother, most quickly removes the fetus and placenta, considering the life of the child a negligible quantity, as it is almost always lost. With the emptying of the uterus, however, not all the danger is over, for the hemorrhage may persist, not only from atony of the organs, but also from the fact that in certain areas blood has penetrated

the muscle bundles, disassociated the fibers and rendered them absolutely incapable of contraction. Therefore, in cases of doubt a hysterectomy is the safest procedure. The prognosis is most grave, for with the best of treatment the maternal mortality is about 60 per cent., while the fetal is about 90 per cent., and should the patient fortunately survive, her after-treatment will demand for some time the utmost care and attention.

3. Post-Salvarsan Jaundice.—A. T. Todd, Major, R.A.M.C., Consulting Physician, Rhine Forces, records observation on twenty-four cases of "914" jaundice, and as controls fifteen cases of jaundice in patients who were nonsyphilitic and had not had any arsenical treatment. The investigations made include clinical findings and narration of symptoms, as these differ from those found in catarrhal jaundice, and are therefore of importance in differential diagnosis. The urinary investigations comprise examination of the amount, acidity, presence of albumin, casts, sugar, acetone, deposit of leucin and tyrosin, bile pigments and acids, urobilin, percentage of urea, estimation of ammonia, and the ammonia-urea nitrogen ratio. The diastase was estimated in each case from time to time. These examinations were made daily until convalescence was established. All the quantitative and most of the qualitative examinations were made by the writer with the same apparatus throughout. The urinary findings justify the opinion that a lesion of the liver tissue is present and that an acidosis results; for 80 per cent. of the cases showed evidence of acidosis at some period of the illness. Moreover, the degree of acidosis was proportional to the severity of the clinical findings; also the acidosis disappeared as the other symptoms subsided. The character of the symptoms in the two classes of cases ("914" jaundice and catarrhal jaundice) show no marked differences, with the exception of abdominal pain, which in the "914" group showed no relationship to food; in three cases, all showing definite evidence of liver enlargement, the pain was dependent upon posture, being aggravated by lying upon the left side. Pyrexia was not observed; the one fatal case showed a sub-normal temperature. The skin desquamation affected chiefly the extensor surfaces of the limbs; in a few cases the trunk, especially the chest, showed scaling; there was no associated dermatitis. In the "914" group the liver was definitely palpable and enlarged in 38 per cent. of the cases; other changes were noted. The liver condition changes with the progress of the case. Somnolence was noted only when distinctly more marked than the depression and lethargy common in other forms of jaundice. The average of the cases shows that the period spent under close observation was 22 days; about three days added to this gives the average time spent in hospital. The last day after admission on which acidosis was present averaged the fourth day. No case was discharged from hospital until he had been on the full diet for a week, and had performed some light duty. Up to the time of the report no relapses have occurred. All the cases were kept in bed until diet, including chicken, was ordered. The only routine drug treatment given was sodium bicarbonate, 60 grains t.i.d.s. Laxatives were ordered when required. For 24 hours after admission full diet and no treatment was given in order that the gravity of the case could be determined. After this the patient was put on the following diets, one after another, as the urinary and clinical findings improved: (1) Starch diet; (2) fish diet; (3) fish and eggs; (4) chicken diet; (5) ordinary diet. Recovery of the jaundice controls likewise appeared to be accelerated by this treatment.

5. Acute Puerperal Salpingo-peritonitis.—Aleck W. Bourne explains the use of the term which lays due emphasis on the peritoneal factor in the pathology and treatment, whereas "salpingitis" is not enough, while "salpingo-oophoritis" is often wrong, especially early in the disease. Further, he is chiefly concerned with acute salpingitis, occurring in a previously healthy tube, which is more common than is generally supposed, and which gives rise to the characteristic clinical picture which he describes. It is known that the disease is due either to extension of organisms along the tube from the infected uterus or to an exacerbation of previous salpingo-oophoritis, which must of necessity have been only slight in degree or unilateral. That the former does frequently occur is certain, and can be easily understood; but that the disease may be caused by organisms that have lain dormant for a long time in otherwise perfectly normal tubes is proved by a case cited. Puerperal salpingo-peritonitis should be operated upon as early as the diagnosis is established. The general principles in operating are to employ conservative measures on structures in an acute condition in order, first, to save them, and secondly, to prevent chronic changes developing in them, but to deal radically with acutely inflamed and seriously damaged appendages in spite of dense adhesions which may be present. In this way very much can be done to conserve function, to prevent chronic disease, and to provide for a reasonably quick recovery to normal health.

2. Glandular Fever.—H. Lethby Tidy and E. B. Morley record the observation of three cases and review the findings of other clinicians. This rare condition is an acute infectious disease principally of children, characterized by rapid enlargement of the cervical glands and by a less constant enlargement of the liver, spleen, axillary, inguinal, and other glands. The incubation period is from five to ten days. The onset is sudden, with the usual symptoms of an acute pyrexial attack in children; restlessness, loss of appetite, constipation, furred tongue, rapid pulse, and occasionally vomiting. Abdominal pain is sometimes present, and may be severe. Enlargement of the lymphatic glands may be present with the earliest symptoms, or it may develop rapidly within twelve to forty-eight hours. The glands constantly affected are the cervical, deep to the sternomastoid muscle about the middle of its length. The enlargement is marked, and produces a definite swelling of the neck. The cervical enlargement is commonly unilateral at the onset. The parotid and submaxillary glands are not affected. Enlargement of the axillary and inguinal glands has been noticed by most observers. Enlargement of the mesenteric glands may occur, and is accompanied by abdominal pain. There is some evidence that the peribronchial glands may be involved. The tonsils and pharynx may be involved. No rash accompanies the condition. Epistaxis and vomiting may occur at the onset. The pulse may be rapid, while the temperature is high, but cardiac complications do not occur. Constipation may be severe, and may terminate with diarrhea or with the discharge of slimy motions at the end of the first week. The liver and spleen are enlarged in a considerable proportion of cases. The temperature usually rises to 101° to 103°, occasionally to 105°. Bacteriological investigation has been directed principally to cultures from the fauces, resulting in the growth of streptococci, staphylococci and pneumococci, with influenza bacilli in a certain number of cases. Complications are rare, and the prognosis is favorable. In the acute stages only symptomatic treatment is necessary. If the cervical glands are painful, compresses, hot or cold, may be applied, or glycerin of belladonna. Constipation should be treated by simple remedies, and there is no indication for the drastic methods recommended in the past. As convalescence is often

prolonged, as some degree of anemia may develop, and as a poor state of health may persist for several months, care must be taken, especially with delicate children, and tonics of iron and cod-liver oil and malt should be administered. There is no reason to believe that nephritis becomes chronic, but it is advisable to treat it with the same care as an ordinary nephritis. Glandular fever must be regarded as infectious, and patients should be isolated. A period of fourteen days may be suggested for isolation and a similar period for quarantine.

3. Comments on the Diagnosis of Acute Abdominal Conditions.—Frank D. Jennings states, as his own experience, that errors in diagnosis are most often due to failure to get a good history, or failure to interpret symptoms and physical findings because a certain picture is carried in mind, or in some few instances a superficial examination or none at all. Even with careful history taking, careful examining, and careful case analysis, mistakes will occur. He cites a few illustrative cases, and emphasizes that rigidity is not an essential concomitant of acute abdominal diseases, that pain is always a symptom demanding attention and respect; that the pelvic appendix does not behave in the classical way; that the stereotyped text-book description of ectopic is often seen in the case that is not ectopic; that lumps in the femoral region in women of advanced years, no matter how trivial or innocent they may seem, are generally femoral hernias, and that lesions of the abdominal wall may present symptoms suggestive of intraabdominal disease.

1. The Significance of the Bacteria Found in the Throats of Healthy People.—Arthur L. Bloomfield states that during the course of studies on the fate of bacteria introduced into the upper air passages it became apparent that foreign organisms were rapidly eliminated. It seemed probable, therefore, that the true normal flora of these regions might be relatively simple and constant, and that, if it could be clearly defined, a background could be obtained against which the flora present in various disease conditions might reasonably be contrasted with less chance of misinterpretation. For example, should it turn out that the green streptococcus is constantly present in normal throats, its presence in disease would have to be interpreted with great caution, whereas an organism not normally present in healthy throats, if persistently found in a given individual, would indicate disease or at least an abnormal carrier state. It immediately became clear that a large number of single cultures from various individuals would help but little in the solution of this problem. It appeared more hopeful to study the flora of a few individuals repeatedly at frequent intervals over a considerable period of time, as by this means one could determine not only the organisms present, but their persistence as well as their relative predominance. Moreover, chance temporary

invaders could be distinguished from bacteria actually dwelling in the mouth cavity. Six healthy individuals were selected for this study, from which it was concluded that the organisms present in the throats of healthy people, as revealed by the method described, fall into two groups: (a) The true normal flora including non-hemolytic streptococci and Gram-negative cocci, and (b) Pathogenic or nonpathogenic organisms which are accidentally introduced and are present usually only a short time in a given individual. A true picture of the normal flora is obtained only by making repeated cultures from the same individual.

2. Experimental Inoculation of Human Throats with Avirulent Diphtheria Bacilli.—Moss, Guthrie and Marshall hold that, for a proper appreciation of the relation of the healthy diphtheria bacillus carrier to the community, it would be helpful to know which persons are actually carriers or at least the approximate proportion of carriers in the population at large. Next, it obviously would be of practical importance to ascertain whether any cases of clinical diphtheria develop among the associates of these carriers. Feeling that the results of animal experiments, previously reported, might not be entirely applicable to man, further experiments were carried out, this time with human beings instead of animals as subjects, the object being: 1. To determine whether the introduction of avirulent diphtheria bacilli into the throats of healthy human beings will result in the production of the carrier state and, if produced, how long it may last. 2. To determine whether the lodgment and growth of the bacilli may be prevented by the previous injection of diphtheria antitoxin. 3. To determine whether the organisms introduced are capable of producing (a) clinical diphtheria; (b) any subjective symptoms; (c) any objective signs in the appearance of the throat. 4. To determine whether any cases of clinical diphtheria develop among the associates of artificially produced "healthy carriers" of virulent diphtheria bacilli. 5. To determine whether the organisms introduced into the throats of normal human beings are in any way changed by this procedure, particularly as to (a) morphology; (b) staining characteristics; (c) cultural characteristics; (d) ability to produce toxin (virulence). The following points are emphasized as the result of these experiments: From the results of the experiments herein reported certain facts seem sufficiently important to warrant repetition for the sake of emphasis. (1) The carrier state was easily produced in human beings by inoculation of the throat with avirulent diphtheria bacilli. (2) When thus produced the carrier state lasted for a long time; two of the carriers still harbored avirulent diphtheria bacilli after 15 months. (3) The previous administration of diphtheria antitoxin subcutaneously did not prevent the lodgment and growth of the organisms. (4) Inoculation of avirulent diphtheria bacilli into the throats of human beings did not produce: (a) clinical diphtheria; (b) any subjective symptoms; (c) any objective change in the appearance of the throat. (5) The results of the guinea pig test for virulence were confirmed when thus tested with human beings. (6) No cases of clinical diphtheria developed among the associates of these artificially produced "healthy carriers" of avirulent diphtheria bacilli. (7) When isolated in pure culture after prolonged sojourn in the human throat, the bacilli were not altered in morphology or in their staining or cultural characteristics. (8) The bacilli showed no tendency to become virulent as a result of this type of animal passage, either in the carriers who had received diphtheria antitoxin or in those who had not. (9) Spraying the nose and throat with gentian violet in a strength which could be tolerated seemed to be without effect in eradicating avirulent diphtheria bacilli. The results of this experimental inoculation of the throats of human beings with avirulent diphtheria bacilli are in entire accord with those obtained in their previous work—with healthy diphtheria bacillus carriers. The same general conclusions drawn from their earlier work have merely been confirmed and somewhat amplified: 1. Avirulent diphtheria bacilli retain their characteristics despite long residence in the human throat or transfer from one human being to another. 2. Avirulent diphtheria bacilli are devoid of pathogenic importance for man. 3. The carrier of avirulent diphtheria bacilli is not a menace to the community.

Book Reviews.

MANUAL OF SURGERY (ROSE AND CARLESS) FOR STUDENTS AND PRACTITIONERS. Tenth Edition. By ALBERT CARLESS, C.B.E., M.B., M.S. Lond., F.R.C.S. Colonel (Temp.), A.M.S.; Consulting Surgeon, Eastern Command; Emeritus Professor of Surgery to King's College, London, and Consulting Surgeon to King's College Hospital; Formerly Examiner in Surgery to the Universities of Glasgow, Manchester, Liverpool, and Leeds, and to the R.A.M.C.; Medical Director, Barnardo Homes, etc. New York: William Wood & Co., 1920.

For a work to get to a tenth edition means that the purchaser gets something worthwhile and that the book has not flourished simply on the sometimes evanescent popularity of its author or authors. This is one of the best known and liked works on surgery in the English language, and the present edition represents all that is best.

It is five years since the last revision, during which time the world war has been fought and won. The lessons of this war have made a great deal of revision necessary; for, as Carless says in his preface, "many an old surgical practice has been tried and found wanting and had to make way for younger and more efficient methods." It is not only in the chapters where injuries due to shot and shell are considered that changes in the text have been made necessary, but in the treatment of infected wounds, the treatment of fractures, the handling of joint injuries, the surgery of the chest, cosmetic surgery, and in many other fields formerly accepted methods of treatment have been improved or superseded altogether. To revise large portions of the work on this basis has been a hard task, particularly since, as Carless says, he has been brought face to face with the task of determining the ultimate value in civilian work of the many and diverse methods which have been introduced as wartime emergencies. Time alone will tell how accurately the author has gauged the value of these expedients; but it seems to us that he has used excellent judgment and has been particularly successful in sifting the wheat from the chaff, so that comparatively little will have to be discarded when another edition is demanded.

From the first chapter, on surgical bacteriology, infection, and immunity, through the various chapters covering the so-called principles of surgery and surgery proper, to the final chapter on military surgery, the text is well written and dependable; and the book retains its enviable position as one of the best textbooks on its subject extant. The size of the page has been reduced slightly, to no apparent advantage that we can see and to the detriment of the appearance of the book as it stands on the shelf with others; so that it is to be hoped that when another edition appears the page will be restored to its former size.

TEXT-BOOK OF NERVOUS DISEASES FOR THE USE OF STUDENTS AND PRACTITIONERS OF MEDICINE. By CHARLES L. DANA, A.M., M.D., LL.D., Professor of Nervous Diseases in Cornell University Medical College; Consulting Physician to Bellevue Hospital; Neurologist to the Montefiore Hospital; Neurologist to the Woman's Hospital; Consulting Physician to the Manhattan State Hospital; Ex-President of the American Neurological Association; Ex-President of the New York Academy of Medicine; Corresponding Member of the Société de Neurologie, etc. Ninth Edition. With Two Hundred and Sixty-two Illustrations, Including Four Plates in Black and Color. New York: William Wood and Company, 1920.

For nearly thirty years this has been a standard textbook; and for the medical student and general practitioner there is probably no better book on the subject. The present revision has enabled the author to incorporate the modern advances, some of which were acquired in the late great war. Shock, emotional strain, and injuries to the nerves are some of the newer topics presented; there is also a chapter on psychology, in its dynamic, descriptive, and physiological phases, emphasizing those fundamental things which every student ought to know in order to reason clearly on the subject. A chapter has also been added on encephalitis

lethargica. We would strongly advise all readers of the work to include the two prefaces in their study of the book; the original preface gave a careful selection of the more important nervous diseases, and thereby also indicated what were of lesser importance. This method of elimination is of great value for educational purposes, and the author's brief allusions to psychoanalysis in the text and in the new preface are as illuminating as any long discussion of that subject could be, and are probably more serviceable. The student will find here almost all of the newer work which has proved of value, and in the use of this book will acquire a knowledge of nervous diseases which is sound and serviceable. The book is very readable, it is of moderate size, and it is sanely conservative, while thoroughly up to date.

THE FORM AND FUNCTIONS OF THE CENTRAL NERVOUS SYSTEM. An Introduction to the Study of Nervous Diseases by FREDERICK TILNEY, M.D., Ph.D., Professor of Neurology, Columbia University; Attending Neurologist, the Presbyterian Hospital and the New York Neurological Institute; Consulting Neurologist, Roosevelt Hospital, New York, and HENRY ASLOP RILEY, A.M., M.D., Associate in Neurology, Columbia University, Associate Attending Neurologist, New York Neurological Institute; Attending Physician, Neurological Department, Vanderbilt Clinic, New York. Foreword by GEORGE S. HUNTINGTON, Sc.D., M.D., Professor of Anatomy, Columbia University. New York: Paul B. Hoeber, 1921.

This work is new of its kind in that it is a treatise on the anatomy and physiology of the central nervous system in their relation to clinical neurology. It has been written as a result of the author's experience in teaching neuroanatomy in Columbia University and to members of the Army Medical Corps during the late war. To make the teaching of practical value they aimed to keep always in view the relation of the anatomy and physiology of the central nervous system to the clinical manifestation of the lesion there located, and they found the difficulty of their task greatly increased by the lack of a book such as the one now completed. It is a monumental work, in both size and substance, 1020 pages with 763 illustrations covering only the central nervous system—spinal cord, medulla and brain—but covering it in a way that has never been done before even by a toiling and detail-loving Teuton. It is not, manifestly, a book for the anatomical student in his early encounter with cerebral anatomy, but for the recent graduate with an abundance of time, an hour a day given to conscientious and concentrated study of its pages will give him an insight into the intricacies of the brain and medulla and the causal relationship of lesion and syndrome which will stand him in good stead throughout his professional life to whatever branch of medicine he may devote his energies. The man already in practice will find this an invaluable work of reference which will give him the solution of many a knotty problem. The illustrations, many of them colored, are excellent and add immensely to the ease of comprehension of the anatomical descriptions and of a grasp of the various lesions and their corresponding syndromes.

AN INTRODUCTION TO THE STUDY OF HYPNOTISM, EXPERIMENTAL AND THERAPEUTIC. By H. E. WINGFIELD, M.A., M.D., B.C., Cantab. Consulting Physician, Royal Hants County Hospital, formerly Demonstrator of Physiology in Cambridge University, Ex-President Psycho-medical Society. Second Edition. New York: William Wood and Company, 1920.

BEING an introduction, this book does not propose criticism of the various theories; but it does state the problems presented and discusses them with fairness. It aims to provide the reader with sufficient theoretical and practical knowledge to enable him to use suggestion in suitable cases. In its closing chapter it deals with "Repressed Memories" in common-sense fashion and is therefore most useful. It succeeds in its aim of being an introduction to a subject which needs to be properly understood both by reason of its utility when properly used, and of its risk by exploitation in ignorant and unscrupulous hands.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held January 20, 1921.

THE PRESIDENT, DR. GEORGE DAVID STEWART, IN THE CHAIR.

THE program of the evening was arranged in cooperation with the Section on Obstetrics and Gynecology.

The Administration of Pituitrin at the Beginning of the Third Stage of Labor in One Hundred Consecutive Cases.—Dr. GEORGE H. RYDER presented this paper, in which he said that the third stage of labor had always been a matter of concern to the obstetrician, because at any time during this period hemorrhage might occur. It might occur in any kind of labor, even in the easiest and apparently the most normal. Several methods were in use for preventing hemorrhage during the third stage of labor and for insuring the complete expulsion of the placenta: (1) The fundus was left entirely alone and untouched, and after a certain time the placenta was expressed by Credé. This method was mentioned only to be condemned, for it seemed too uncertain and haphazard. (2) The obstetrician looked after the fundus himself, putting his hand on the patient's abdomen after birth of the baby; he located the fundus through a sterile towel, and by holding it and gently tickling it with his finger tips when it started to relax he could keep it well contracted and prevent hemorrhage. Finally, at the appropriate time, usually in from ten to twenty minutes, he could cause the expulsion of the placenta by using Credé's maneuver. Unfortunately, he could not often use this method, for the new born child claimed his attention. He must see that it cried well, tie, cut, and dress the cord, and attend to the baby's eyes. These duties might be delegated to an assistant, but they were of so great importance that the obstetrician usually felt obliged to attend to them himself. Therefore the third method was used. (3) The obstetrician felt the fundus from time to time, as he was able through a sterile towel, and for the rest of the time, until he had attended to the baby, he intrusted the care of the uterus to a nurse or assistant. Unfortunately few nurses knew how to hold a fundus in the third stage of labor, and even of the doctors themselves many were almost equally ignorant. Except for a few who had had unusual experience, practically all nurses failed to locate the fundus at all, and spent their time holding on to, or actively massaging the patient's abdominal wall, while the fundus was riding above their hand entirely untouched. Or, if they did locate the fundus, they lost it as soon as it softened and relaxed, a time when it especially needed attention to prevent hemorrhage. Again, when the fundus was hard and well contracted, they persistently rubbed and prodded it. This tended to cause premature and incomplete separation of the placenta with bleeding. (4) The use of ergot in the third stage of labor was of little advantage and even dangerous. It was slow and caused a continuous tonic contraction of the uterine muscle, and if that happened before the placenta was expelled, the uterus might clamp down tight upon it and make expulsion difficult, even causing hour-glass contraction. It was a safe rule that ergot should never be used until the uterus was empty. (5) The use of pituitrin in small doses in the third stage of labor acted to produce not tonic contractions but clonic contractions, contraction followed by relaxation. This might be safely used on a uterus that was not empty; its action was much more rapid than that of ergot, and when given hypodermically it acted in from two to seven minutes, but continued its action only twenty to thirty minutes. For years it had been his routine practice to have a hypodermic syringe filled with 1 c.c. of pituitrin, ready during the third stage of labor. On the first sign of undue hemorrhage this dose was given hypodermically, and shortly after, when the uterus was felt to contract firmly, the placenta was expressed by Credé's maneuver. This was followed by a drachm of ergotole by mouth. Many observers had reported good results from the administration of pituitrin at the beginning of the third stage of labor, as a routine, claiming that the management of this stage was thus made

easier, and the satisfactory expulsion of the placenta was made surer. With a view of testing this method, it was tried on 100 ward patients at the Sloane Hospital for Women during the summer of 1920. Irrespective of the kind of labor or of the condition of the patient, each woman at the beginning of the third stage was given 1 c.c. of pituitrin by hypodermic injection. The fundus was then held for twenty minutes, unless the placenta was expelled spontaneously before that time. No attempt was made to express it sooner. For comparison 100 other labors were observed in which pituitrin was not used, at the beginning of the third stage. Of the 100 cases receiving the pituitrin, 86 were normal vertex deliveries; 80 had no medication, pituitrin or ergot, after labor, and showed no need of it; 20 had either pituitrin or ergot after labor, because they did show need of it; in 25 the placenta was expelled spontaneously before 20 minutes; in 75 it was expressed by the Credé at the end of 20 minutes; in 74 with slight pressure. All of the 100 placentas came away complete. None needed manual extraction. There was no hemorrhage of the first degree, namely, 16 ounces, the average amount being 5.9 ounces. After labor the fundus was observed to remain hard for one hour in 93 of the 100 cases. Of the 100 non-pituitrin cases, 88 were normal vertex deliveries; 45 needed pituitrin or ergot post-partum; none of the placentas were expelled spontaneously; 98 were expressed by the Credé easily; two placentas were extracted manually. The hemorrhage was slightly greater than in the non-pituitrin cases, an average of 8.2 ounces. In the puerperium 60 had no temperature at any time of 100° F. or over, as against 74 in the pituitrin series; and 40 did have temperature at some time of 100° F. or over, as against 26 in the pituitrin series. The writer also reported a series of 7 private patients in which he used this method. He concluded that while the series was too small to allow of definite deductions, it was a safe procedure; it tended to spontaneous expulsion of the placenta; it tended to lessen the amount of blood lost; it made guarding the fundus during the third stage easier, though it did not do away with the necessity of watching or holding the fundus; it was probably better not to wait twenty minutes as a routine before trying to express the placenta, as was done in this series. He believed the method worthy of further study and consideration.

Dr. WILLIAM E. CALDWELL said that one hundred cases in which pituitrin was used as soon as the baby was born did not prove that the pituitrin would never cause trouble. But Dr. Ryder certainly had shown that its use was safe as a routine in the majority of cases. There were no cases of really adherent placenta in Dr. Ryder's series. He thought an adherent placenta was comparatively rare, but it certainly did occur, and it was conceivable that the pituitrin might make the manual extraction more difficult. In such a case it might be better to wait until the action of the pituitrin had passed. Or, if there were a partial separation with bleeding, under chloroform anesthesia it should be possible to overcome the action of the drug. Dr. Caldwell believed an adherent placenta should be removed manually and the uterus packed. Having seen some of Dr. Ryder's cases, and having tried it on some of his own, he believed the uterus acted very much much better during the third stage when pituitrin was used. It did not balloon up as much, and therefore it was easier for the nurse, with her fingers on the fundus, to keep track of its condition, without constantly losing the uterus. In multiparae the speaker was disposed to believe that there were fewer after-pains if pituitrin was used in the third stage. Before Dr. Ryder began his experiments he thought it possible that there might be relaxation of the uterus after the effect of the drug had passed. Very few of Dr. Ryder's cases required a second dose of pituitrin or ergot to keep the uterus in good condition.

Dr. RALPH W. LOBENSTINE stated that he had been using pituitrin in the third stage of labor in upward of 115 cases. His practice had been to administer 5 minims directly after the birth of the child and from five to eight minutes after the expulsion of the placenta. The only modification of this dosage was that in those cases with a history of sudden violent hemorrhage in the third stage a full ampoule of the drug had been

given at the first dose, this being followed, after the expulsion of the placenta, with one ampoule of aseptic ergot. Dr. Lobenstein said he was still old-fashioned enough to believe in holding the fundus during the third stage of labor and in gentle massage in case of relaxation. His nurses were taught to do this correctly, and he or his assistant verified this from time to time. His patients in this series had all been private patients, many of them in rather delicate health—women requiring close watching, in whom the unnecessary loss of six or eight ounces of blood was often of real significance. He had not noticed that the placenta was expelled any more quickly by this method, nor did he agree with Dr. Ryder that it was an advantage to have it expelled quickly. This method certainly seemed to lessen the amount of blood lost, but it caused at times a disagreeable amount of pain during the first twenty-four hours post partum. He did not think the method should be generally used. For average cases it was unnecessary; it was expensive and it might be dangerous.

The Least Common Multiple in Obstetrics.—Dr. HERBERT M. LITTLE of Montreal made this presentation. He showed that the views expressed by the modern novelist, if taken as those ordinarily accepted by the laity, would suggest that the average woman entered upon pregnancy not only with a dread of the outcome for herself and baby, but with the practical assurance that, even should both survive, the ordeal would be a terrible one. He questioned whether this point of view was justifiable and whether it was not time to take counsel together, with a view to improving their work, if at all possible, and placing before the public the results of the proper handling of maternity cases, the infrequency of maternal deaths, and the relative unimportance of childbirth as a cause of maternal death, when there had been sufficient prenatal care. The methods in use at the Montreal Maternity today were simpler than at any time since that institution was opened, and the results, so far as he could classify them, better than at any period since that date. It was to a consideration of a simple routine—the smallest possible combination of all that was best—the least common multiple of methods—that he would invite attention. Maternity was a test of function, and pregnancy should be a perfectly normal state for a normal woman. Beyond the injunction to drink plenty of water, to be sure that there was a daily evacuation of the bowel, and to massage the nipples in order to facilitate nursing, little advice was necessary. Apart from relatively frequent examinations of the urine, he believed the best thing to do was to leave the patient alone as much as possible until within the last month. Why they should not ride, rolf, or swim he had never been able to understand, and, aside from being told to be careful at such times as menstruation would take place were they not pregnant, they were allowed every freedom. The three chief complications of pregnancy from the standpoint of the practitioner were vomiting, toxemia, and pyelitis. Personally he believed that there was no such entity as the pernicious vomiting of pregnancy; that to severe vomiting early in pregnancy there were sometimes added the toxic results of acute starvation, which was not remarkable, but in twenty years he had seen no more than five cases in which the emptying of the uterus was necessary or justifiable. He had found that, even where vomiting had assumed rather serious proportions, it had always been possible to prevent starvation by the administration of such foods as were not easily vomited; and a great many patients had found early relief when placed on a diet of nuts, raisins, and milk chocolate. The passive congestion induced by wearing a band about the neck before the patient left her bed was also a help and had given remarkably good results. It might be objected that these were methods of suggestion. Perhaps so. The addition of a hypodermic injection of corpus luteum extract could do no harm and had a therapeutic basis. During the past five years they had had many more cases of pyelitis than formerly, and the surprising thing was that so few were recognized outside the hospital. In the treatment of this complication they avoided catheterization wherever possible, and where postural treatment, large doses of urotropin, and forced fluids failed, and the patient's condition became aggravated and there were recurring chills, they had no hesitation in emptying the

uterus. They had been able to do a very little with the nephritis toxemia of pregnancy. In the management of labor the pelvis was the most important factor, but the present division of pelvis into normal and contracted led, he believed, to many unnecessary difficulties. Pelves, even when normal, might be disproportionate, and the so-called contracted pelvis were only an obstruction to labor if disproportionate to the size and shape of the child which was to pass through the canal. Exact pelvimetry was not a substitute for antepartum examination of presentation and position and careful watching of the child in the second stage. It was perfectly true that when the bi-ischial diameter fell below 8½ cm., the birth would be abnormal. Here, the biparietal diameter of an average head must lie behind the bi-ischial line; and if forceps was applied, the entire instrument must lie posterior to the attachment of the transversus perinei muscle. A realization of the danger of extensive damage to the soft parts, together with the relative certainty that the head could pass the pelvis, indicated either deep episiotomy as a preliminary to a spontaneous birth of the head or the application of forceps, with the distinct understanding that a laceration involving the rectum was almost inevitable. The ability to repair satisfactorily such laceration, however extensive, was, he believed, the hallmark of a competent obstetrician. In discussing the question of operative interference, Dr. Little said he did not believe version was a desirable operation in the case of a primipara, and in the case of a multipara he believed it always attended with the grave risk of extensive laceration of the cervix. On the other hand, when the head was arrested in the pelvis and force exerted by the abdominal muscles seemed insufficient to cause the head to advance, his suggestion would be that operation should be performed when it was believed the moment had arrived when the reparable damage that might result from the operation was less than that which would result from allowing the labor to proceed normally. The gravest danger in the labor of any primipara was an overstretching of the recti muscles with resultant increased dystocia in subsequent labors. The causes of maternal death were most closely associated with two complications, infection and hemorrhage. In order to lessen the occurrence of these, three factors in labor deserved special consideration: (1) Rectal examination; (2) median episiotomy; and (3) absolute discontinuance of any medication after the delivery of the child. This included the discontinuance of purgation and the administration of ergot. Non-massage of the uterus allowed a more regular and uniform contraction than where it was held or massaged, and as a result the placenta separated more easily and there was no tendency, by forcing the organ with the membranes protruding from the cervix into the vagina, to smear organisms from the posterior fornix and vagina over the cervix when the placenta eventually separated. The placenta was allowed time to separate, the patient regaining consciousness and separating it by her own efforts. Where episiotomy was performed the sutures were then tied and the fundus watched. It was true that a certain amount of clot might form in the cavity, but at the end of a half hour this was expressed and by that time the formation of thrombi at the placental site had taken place and the patient was secured from further danger from this variety of concealed hemorrhage. Dr. Little advocated emptying the bladder as a matter of routine with the laying of the sutures, since this not only allowed of better contraction of the uterus, but the possibility of later catheterization was markedly minimized. They had been following Dr. Ross McPherson's plan of the non-administration of purgatives during the puerperium, and found that patients who did not have purgatives ran a much smoother clinical course. He advocated the method if for no other reason that the lessening of the amount of care required by the normal case and the resulting increased time of the nurses for the care of those patients who were seriously ill. In the last five years, in some thousands of cases passing through the Montreal Maternity, they had had not more than five breast abscesses and none of these was in the public service. For this, he believed, two factors were responsible: (1) The abolition of breast pumps, and (2) the discontinuance of any special treatment of the nipples other

than care for cleanliness. Occasionally there might be collections of fluid in the breast, which for the surgeon had all the earmarks of distinct abscess, but massage toward the nipple would almost invariably free the duct, and putting the breast at rest for twenty-four hours would effectively prevent the breaking of the capsule surrounding the gland tissue and the involvement of the fatty tissue of the breast. Not infrequently patients complained of pain in the breast, a fluctuating mass, and high temperature. In these cases a piece of white absorbent cotton was the indicator. Ordinary milk would not stain the cotton, but the content of the distended sac invariably showed a dirty greenish yellow. For further involution, hot vaginal douches of formalin were given on the ninth day. Intrauterine douches, he believed, did harm, and he never gave them immediately after labor, but he had used them not infrequently on the fourteenth day where there had been mild infection and rather profuse lochia and a boggy uterus at the examination for discharge. The treatment of the cord was emphatically to leave it alone. Results from the use of a plain dry dressing had been more than satisfactory, better than when alcohol was used.

Dr. JAMES CLIFTON EDGAR expressed the opinion that what had been said about pituitrin was very much to the point and very valuable. Broadly speaking, he was opposed to the use of any drug during labor, and while pituitrin was most valuable and he made it a point always to have it ready for use in private practice, he would hesitate to use it as a routine. His chief objection to its use as a routine procedure was that it caused so much after-pain. One almost always had to follow it with some sedative in order to control the terrific after-pains that would not permit the woman to sleep. Another objection was uncertainty as to its action. He had tried different preparations and had come to the conclusion that its action was to a considerable extent dependent upon the susceptibility of the patient. Some patients it did not act upon at all, and in others it acted out of all proportion to what one would have expected. Its excessive action was open to great objections. Dr. Edgar said he was accustomed to giving one drachm of ergot after the third stage. He was opposed to any medication during labor without pretty definite indications. If asked what he considered a positive indication, he would say what was indicated for the comfort and safety of the patient. He had given pituitrin at the end of the third stage and repeated it at the end of two hours, and that was all. He did not see why one should pitch on a certain time for the expulsion of the placenta; he did not see why one should fix on twenty minutes. He thought if necessary one should wait sixty minutes. Pituitrin offered a tremendous advantage in allowing the obstetrician to give more attention to the baby, but it took only a few minutes to care for the baby. He was quite in accord with the statement that the average nurse did not know how to hold the fundus. He thought it was the obstetrician's duty to watch the fundus. Dr. Little's paper was most interesting and he had touched upon some tremendously important questions. The speaker was not prepared to throw overboard lateral episiotomy, though he thought it looked as though Dr. Pomeroy's contention was correct that the median episiotomy was the proper one. He had seen patients come back in whom it was hard to find the incision, though that did not mean that the muscles beneath were not torn. The claim was made that with the lateral incision one cut into the belly of the levator and on one side. He felt that, on the other hand, there were many advantages connected with the lateral incision, especially the healing and the lessening of the danger of cutting into the rectum. He wished Dr. Little would speak of the extension of the incision into the gut, for there must have been some such accidents without question. He liked what was said about anticipating trouble and not doing anything unless there were positive indications. There was, however, something more than that. It was the duty of the obstetrician to anticipate emergencies and not to wait until a woman had lost a great deal of blood and had a pulse of 120 before preparing to do something. He was quite in accord with what had been said in regard to nausea and vomiting, but was not entirely in agreement about the mild kidney cases requiring emptying of the uterus. In a mild kidney case emptying of the uterus was not

always indicated, and one was often forced to carry these women along, particularly if they were Roman Catholics, and with care, proper diet, and keeping the skin active many could be carried through. Mild kidney lesions might sometimes improve later. He had known instances in which a woman had gone twice to the eighth month and lost her baby, and then in a third pregnancy had gone to full term. Broadly speaking, however, a kidney lesion demanded emptying of the uterus.

Dr. F. A. DORMAN said that Dr. Little in his paper had covered the whole range of obstetrics. Fortunately all women did not take the view of obstetrics Dr. Little had pictured. Many pregnant women were optimistic and did not think of childbirth as "going through the valley of the shadow." A certain proportion of women thought it was a normal process. Dr. Little stated that the pregnant woman could do pretty much as she liked, but the speaker did not think she could be allowed her usual activities. Some could go through their pregnancy safely, but the woman who played golf and tennis was apt to get herself into trouble, and then she would ask the doctor why he had not told her to avoid unusual exertion. As to the nausea and vomiting, many women understood that a little nibble between meals would avert vomiting, but women who had an extreme aversion to food, unless advised to eat frequently, neglected this precaution and suffered more severely. Pyelitis, Dr. Dorman said, he saw occasionally, but had not been flooded with these cases as Dr. Little said he had been. Very rarely did he see critical cases that demanded emptying of the uterus. Personally he felt that catheterization helped to find the stricture and that the patient responded to temporary drainage. He was a strong believer in the beneficial effects of posture, flooding the system with water, and antiseptics. In every borderline case, if the woman had not had the advantage of treatment, one might try careful diet and elimination, and, if the case was a borderline case, she might be carried through, but these were not the cases that were threatened with eclampsia. Dr. Dorman said he was a believer in rectal examinations and thought one could learn almost everything that way, but there were times when a vaginal examination was useful, and, with surgical care, he believed there need not be much morbidity. He asked Dr. Little how he determined the condition of resistance of the cervix. Rectal examination of the cervix was not of the prognostic value that it would be if one had the finger in the cervix. He also asked Dr. Little regarding the indications for episiotomy, whether one should assume that he was going to lose the perineum and, rather than have the possibility of sewing it up, do an episiotomy. It seemed to him that the tendency at present was to lose heart and do an increasing number of episiotomies. Where there were vaginal tears it was well to proceed to put in the sutures before the patient came out of the anesthetic. By prompt work one might avoid anesthesia in the third stage. Dr. Dorman asked Dr. Little if he did not hold the uterus in the third stage, how he knew that it was not ballooning and filling with blood. What was his rule when he discarded cathartics, and what was his rule in regard to enemas? He used catharsis systematically on the third day, not because he thought the patient could not empty the rectum by an enema, but because he thought the catharsis relieved the distention of the breast. He was heartily in sympathy with doing away with the breast pump. He thought it gave an artificial stimulation to the function of lactation. He also believed that an ordinary lump meant very little and was not a sign of future abscess or mastitis, unless it occurred in the second week and was accompanied by a rise in temperature. The intrauterine douches he had discarded, preferring to use postural treatment, elevating the head of the bed if there was faulty drainage.

Dr. W. E. STUDDIFORD said that it was most important that the pregnant woman should be kept constantly under supervision. The question of determining the measurements of the pelvis and the action of the kidneys and bowels was most important and made for the woman's good health and that of the baby. He also had received a copy of the report from the Metropolitan Life Insurance Company to which Dr. Little had referred. This report proved that there was an increase in puerperal sepsis and a very evident increase in the

toxemias of pregnancy. It was a question whether there was really an increase in the number of cases of puerperal sepsis or whether cases were being recorded more carefully than formerly. When it came to the toxemia of pregnancy there might be several things responsible. In his experience there had been an increase in the number of kidney cases, not eclampsia. It was a question whether the recent epidemic of influenza had not had some effect on these women. It was well known that influenza had affected most persons between the ages of twenty and thirty, and that many attacks of influenza were followed by cardiovascular or renal pathology later on. It was important that such conditions be recognized early so that the pregnant woman could be placed under treatment. Many of the mild types of kidney affections could be carried through, while in others there occurred placental changes and death in utero. As regarded pyelitis, his experience had not always been like that of Dr. Little. Most cases under proper diet, rest, and posture, where there was pressure on the uterus, would be relieved. He was not sure but that many of these cases were due to focal infections involving both the teeth and the tonsils. Contrary to the old idea that no dentistry should be performed during pregnancy, he considered that proper and conservative dentistry was necessary. The statement had been made that in performing episiotomy the levatores ani muscles were cut; that was incorrect. However, he felt that advocating episiotomy as a routine measure was not to be encouraged. Suturing the incision was not the simple thing described; it required a certain amount of skill in surgical technique. He did not believe any harm was done, and many times a great deal of good was done by the judicious use of a cathartic post-partum.

Dr. RYDER said that Dr. Caldwell stated that objection had been made to the use of pituitrin in the third stage of labor on the ground that it made management of adherent placenta more difficult. He did not see why this should be so. The action of the pituitrin lasted only twenty or thirty minutes and the attempt to express the placenta was rarely made before this. If the placenta was found to be adherent, then the action of the pituitrin had already worn off, so that it could have no effect on the condition or treatment. Dr. Caldwell also mentioned the possibility of relaxation of the uterus after pituitrin. A study of this series had not shown any such effect. In ninety-three of this series the uterus remained hard post-partum. In six it hardened and softened alternately, and on only one did it remain soft persistently until another dose of pituitrin or ergot was given. Dr. Lobenstein had said he believed holding of the fundus during the third stage was always necessary as a routine precaution against hemorrhage. He entirely agreed with him. He thought that if those who advocated leaving the fundus alone during the third stage could have the amount of blood lost actually measured in each case they would be surprised to see how much it was. Hour-glass contraction was not seen in any of this series. In one case there was difficulty in expressing the placenta. Three different attempts were made at intervals of twenty minutes, and then under ether it was expressed. In the non-pituitrin series, however, there were two such cases, and in these even the last attempt under ether proved unsuccessful, and the placenta had to be extracted manually. Dr. Edgar and Dr. Lobenstein spoke of pain after the use of pituitrin. He had not seen this, and he had been using pituitrin post-partum for years. Of course, many multiparae had after-pains whether given pituitrin or not, but he believed pituitrin and also ergot lessened this tendency by preventing the formation of intrauterine clots. At any rate, the action of the pituitrin was of such short duration that he did not see how many of the after-pains could be ascribed to its use. He entirely agreed with Dr. Edgar that ergot given post-partum added to the comfort and safety of the patient. Dr. Edgar said he did not like a specified time of twenty minutes for the expression of the placenta, and that he would wait sixty minutes or even two hours. He could see no advantage in waiting such a long time as this as a routine procedure. He believed it would add to the amount of hemorrhage and to the discomfort of the patient. The methods of managing the third stage of labor were not at present entirely

satisfactory. They caused the obstetrician much worry, they were not understood by the average nurse, and they allowed unnecessary hemorrhage. The administration of pituitrin at the beginning of the third stage of labor was an attempt at finding a more satisfactory method.

Dr. LITTLE, in closing the discussion, said he regretted that in his brief paper he had omitted a number of things which had been brought up in the discussion. In the nephritis cases he did not mean that all pregnancies should be terminated, but few nephritics with a history of one or eight months' premature delivery showed improvement in a future pregnancy or carried the child for a long time. In such patients one could never fix the time for the induction of labor. In the first pregnancy one should allow the woman to carry the child as long as she could and do everything to help her. While it was more or less hopeless, it was worth while trying. He had never been able to bring through to term a nephritic who had had two previous miscarriages. The blood pressure remained high and there were infarction and thrombosis of the placenta. In regard to golf, tennis, etc., he did not mean that the woman should take unusually violent exercise, simply that she might do the things that she was accustomed to doing. The average woman got down and scrubbed and did all kinds of housework. Why not play golf or tennis? It was impossible to prevent women from doing many of these things except by constant supervision, and he had seen no ill results from freedom. The teeth might bear some relation to the infection of the kidneys. The primary condition, however, was the hydronephrosis, often due to constriction of the ureter by torsion just outside its junction with the bladder. Dr. Little said he had tried both median and lateral episiotomy, particularly if forceps were applied. One heard older obstetricians say they never had had a perineal tear. The pelves of women today were different. They were narrower and there was a closer approximation of the tuberosities of the ischium and a shorter bi-ischial diameter; therefore, a smaller proportion of children could have spontaneous birth. He believed that, if one did an episiotomy and repaired it, the woman was better off in a future pregnancy than if the perineum had been much distended or irregularly lacerated. He had seen some patients go through a second labor after episiotomy without any damage to the perineum. Unless there was considerable bleeding he thought it better to leave the uterus alone, but he did not wait two hours, and how many men did so? Dr. Studdiford said that some of the speaker's patients were uncomfortable without cathartics. Many, he believed, thought they were not getting enough attention. On the whole, it had been pretty satisfactory, and a look at the charts would show that there were fewer rises in temperature in the patients who did not have cathartics. Dr. Dorman spoke of the cathartic being given when the milk was coming in. It used to be thought that the giving of castor oil prevented milk fever. No one today believed in milk fever, and, if the woman was not going to nurse the baby, the milk would go just as quickly if no cathartic was given.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, Held March 9, 1921.

THE PRESIDENT, DR. MORRIS PIERSOL, IN THE CHAIR.

Peritonitis.—Dr. JOHN B. DEEVER read this paper, in which he said that he was not aware that he could offer anything new on the subject of peritonitis, but he agreed with the committee which suggested the topic for the evening's discussion that it was one of such vast importance that it did not suffer from being repeated from time to time, even though its most salient features were probably familiar to all. Aside from the very rare cases of scalled chemical and idiopathic peritonitis which probably represented a hematogenous or lymphatic infection, the most important source of infection in peritonitis was directly from some intraabdominal organ, mainly the appendix, the intestines, the female internal genital organs, the stomach, and the gallbladder, the result either of trauma or disease or both. The first effect of the bacterial invasion was a

hyperemia together with exudation into the subperitoneal tissue of the part around the infected focus, soon followed by exudation of fluid into the peritoneal cavity. This fluid was at first protective and bactericidal in character, but, by impairment of its vitality, it was gradually converted into pus, the rate of conversion being dependent upon the degree of intraabdominal tension, the virulence of the infecting organism and the individual power of resistance. Early in the process, unless the exciting organism was one of great virulence, the resistance of the body and particularly the protective powers of lymph and of phagocytic leucocytes assisted in inducing more or less prompt absorption. But the protective properties of this early turbid peritoneal fluid were lost soon after the serous and seropurulent stages of exudation had passed, and the damaged peritoneal membrane responded by depositing a fibrinous material rich in leucocytes, and thick and tenacious. The effects of this deposit was the coffee-damming of the lymph and blood vessels and cementing the adjacent peritoneal structures together, thus shutting off and isolating areas which were so highly infected as to interfere with absorption and the bacterial action of the exuded fluid. Diffusion we knew was increased by general bodily activity and movements of the diaphragm, and that reduced respiratory force and peristaltic movements were nature's way of preventing diffusion. Practically we made use of this knowledge by putting the body at complete rest and by means of proper posture encouraging the gravitation of the noxious fluids to the lower and less dangerous portions of the peritoneal cavity. By far the most frequent avenue by which the peritoneum became infected was from perforation of some intraabdominal viscus—the most common, of course, being the appendix. But, whatever its origin, the symptoms of peritonitis had much in common. In the order of their occurrence these comprised pain, vomiting, fever, distension, rigidity. The pain, especially in the presence of perforation, was sudden and severe, its intensity varying somewhat according to the organ involved and its pathologic condition. In appendicitis, the most common source of peritonitis, for example, the initial pain was very severe owing to occlusion of the appendicular artery and beginning necrosis. But later when necrosis was complete, the pain lost its severity; indeed, it might subside altogether. This subsidence without doubt was the most serious of the many insidious features of nearly all types of peritonitis, more particularly, however, of appendicitis. The false sense of security aroused was responsible for many of the fatal cases of acute appendicitis. The initial pain was often accompanied by a chilly sensation or a distinct chill, and, in case of perforation, was soon followed by primary nausea and vomiting and the typical reflex rigidity and exquisite tenderness of the abdominal muscles, the latter being usually more marked over the seat of the trouble. The danger of purgation in acute abdominal conditions was one that could not be too frequently emphasized, while it was true that the practice was on the wane among physicians, it, nevertheless, was still entirely too common among the laity, and it was the manifest duty of a general body like the County Medical Society to spread effectual propaganda on this subject. There were, of course, some cases, fortunately few, in which the virulence of the infection was such that nothing that could be done was of avail. And at the other extreme there were mild cases in which the inflammation was transitory and subsided with or without treatment and with or without leaving any trace of its presence. But it was impossible to tell which of such cases would or would not subside, for so much depended on the degree and the type of infection. While the peritoneum could take care of a moderate number of virulent organisms, their presence in numbers beyond the limit of tolerance might result in a dangerous peritonitis, and, if eventually perforation and gangrene developed, the disaster was complete. In a diffuse appendical peritonitis with no definite point of localization and with peristalsis absent, the question of operation was at one time a difficult matter. But with the recognition by Ochsner, Murphy, Fowler and their followers of the value of complete rest and the institution of the now generally accepted treatment which bore their names,

the question as to when to operate was more easily decided. There was, he was aware, a certain class of surgeons who boasted of operating on every case of acute appendicitis no matter at what stage it might be. Dr. Deaver said he had expressed his opinion of this procedure on numerous occasions. He repeated that he who operated in a case of acute diffusing peritonitis after the first thirty-six or forty-eight hours of the onset of the peritoneal inflammation with no evidence of a localizing point was, in the majority of cases, not serving the best interests of his patient, nor his own best interest either, nor that of the profession. In the presence of a circumscribed peritonitis with a definite localizing point of exquisite tenderness, due to an acutely inflamed, perforating or gangrenous appendix, operation could be undertaken in the absence, of course, of constitutional or other contraindications, provided the proper technique was observed with respect to safeguarding the peritoneum from contamination by the proper disposition of gauze packings. Peritonitis the result of intestinal obstruction, gastric, duodenal, gallbladder, intestinal, or colonic perforation, should be immediately operated if the condition could be recognized, which it usually could be if the case was seen early. Too thorough operation in peritonitis too often spelled death. Peritonitis was dangerous directly in proportion to the absorption. It was not the inflammation of the peritoneum that was fatal, but the toxins which were absorbed from the products of the inflammation that caused death.

Dr. ROBERT G. LECONTE said that the surgeon should never forget that the peritoneum was a protecting membrane. It surrounded the viscera, which were subjected to all kinds of inflammation and to traumatism, and its first function, when an inflammation or a trauma damages the underlying viscus, was protective, whether the injury was simply a moderate bacterial invasion or something more severe. In operation the peritoneum should be treated gently, because it was Nature's means of walling off or protecting against the advance of the inflammation. The serum that was thrown out at the point where inflammation started was slightly bactericidal. It was toxin that killed, not what we saw in the peritoneal cavity. Therefore, if operation was undertaken for peritonitis the cause which had produced it must be removed with the least possible traumatism. The moment that was done the operation was over, with the exception of draining the dependent portion if pus was present. If the abscess in the peritoneal cavity was opened one did not have to swab or do anything else. Absolute diagnosis in abdominal catastrophe was not necessary. When the catastrophe occurred, if the surgeon was not in the abdomen within four to six hours every half or quarter hour after that counted against the patient, and if it was going to take a doctor ten or twelve hours to find out that some acute catastrophe had occurred before the patient came to the hospital, and maybe another two or three hours before he got the patient on the operating table, all his patients would die.

Dr. JOHN H. GIBSON said that thirty years ago we all had the belief that the peritoneum was one of the least resisting of the structures in the body. We knew today that the peritoneum was an extremely resisting structure to infection if it was only assisted and was not interfered with. There was no better example of this than the practice in regard to gunshot wounds of the abdomen during the late war, when, toward the end of the war, after enormous experience, the surgeons of all countries had reached the definite conclusion that gunshot wound of the abdomen should be absolutely closed without drainage, unless it was in the large intestines. Such a rule could never have been formulated if the abdomen had not possessed an enormous ability to resist infection. The peritoneum could take care of itself. It was not a question to determine that a patient had a peritonitis, but it was up to the physician and surgeon to say where this peritonitis originated, because the procedure was going to depend upon that. If it originated from a puerperal, from a gonococcal, or gallbladder infection, then operation should not be done. If from the appendix or gastric or duodenal ulcer, you could not operate too soon. When the exudation was swarming with

bacteria, drainage should be employed. Drainage in an early case of exudation of lymph would often mean an infected wound. What was good for peritonitis if you were not operating was good for peritonitis if you were operating. He did not think morphia in any way interfered with the patient's recovery.

Dr. CHARLES F. NASSAU said that there were a multitude of things that could be confounded with peritonitis, notably pneumonia, locomotor ataxia, or fecal infection.

Books Received.

The MEDICAL RECORD is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.

STUDIES FROM THE DEPARTMENT OF PATHOLOGY OF THE COLLEGE OF PHYSICIANS AND SURGEONS. Columbia University, N. Y. Volume XVII, 1920. Reprints. With Illustrations.

AN INTRODUCTION TO CHEMICAL PHARMACOLOGY. By HUGH MCGUGGAN, M. D. 418 pages with illustrations. Published by P. Blakiston's Son & Company, Philadelphia.

LABORATORY MANUAL FOR THE DETECTION OF POISONS AND POWERFUL DRUGS. By WILHELM AUTENREITH, M. D. 342 pages with 25 illustrations. Published by P. Blakiston's Son & Co., Philadelphia.

DISEASES OF THE LUNGS AND PLEURA. By Sir R. DOUGLAS POWELL and P. MORTON-SMITH HARTLY. 789 pages with illustrations. Published by P. Blakiston's Son & Co., Philadelphia.

SURGERY. Edited by WILLIAM WILLIAMS KEENE, M. D. Vol. VII. Supplementary Volume. 855 pages with illustrations. Published by W. B. Saunders Company, Philadelphia.

DIAGNOSTIC AND THERAPEUTIC TECHNIC. By ALBERT S. MORROW, M. D. 893 pages with 392 illustrations. Published by W. B. Saunders Company, Philadelphia.

THE JOHNS HOPKINS HOSPITAL REPORTS, Volumes XX and XXI. Fasciculus 1 and 2. 559 pages with illustrations. Published by the Johns Hopkins Press, Baltimore.

THE EFFECT OF CERTAIN AGENTS ON THE DEVELOPMENT OF SOME MOULDS. By K. G. BITTING. 176 pages with illustrations.

MEDICAL KNIGHTHOOD.

By W. B. KONKLE, M.D.

MONTOURVILLE, PA.

"A knyght ther was and that a worthy man,
That fro the tyme that he first bigan
To ride out, he loved chivalrie,
Trouthe and honour, fredom and curteisie.

He was a verray parfit, gentil knyght."

Canterbury Tales.

"He, then, that is not furnished in this sort,
Doth but usurp the sacred name of knight."

Part First, Henry VI.

"Ach! es geschehen keine Wunder mehr," plaintively reflects Schiller. Carlyle earnestly exclaims, "The age of miracles is past! The age of miracles is forever here." Surveying with horror its end at the guillotine of the tragic career of Marie Antoinette, Edmund Burke voices this wail of woe—"The age of chivalry is gone. That of sophisters, economists, and calculators has succeeded; and the glory of Europe is extinguished forever." But, as in reply Sir James Mackintosh points out, if the beheading of a queen of France must mark the passing of chivalry, then it surely became extinct two centuries before, when another Mary went to the block—Mary Stuart, Queen of France and Scotland—at a time when it is deemed knighthood was in fullest flower. And so upon occasion does one or another of our patriarchs, some grand Elijah of medicine, disgusted and disheartened by certain conditions and certain doings and certain tendencies within the sphere of professional activity, retire to the wilderness, and sob himself to sleep under a juniper tree! Ah, well!—the angels will never forsake such a man. And when refreshed by the food and drink they bring him, let him repair to the cave on Mount Horeb, where he shall hear from God's own mouth, as did the first Elijah, that there are yet seven thousand who have not bowed the knee to Baal!

No; marvels do not cease. At the Marne the forces of Heaven, intangible, imponderable, in might and majesty were marshalled in the skies, turning against error and wrong the tide of battle, just as of old the stars in their courses fought against Sisera. And chivalry is not dead. Arthur does not idly rest in Avalon—to do so would be to not be Arthur. As of yore in flesh and blood he rode, so at this day in spirit up and down the haunts of men still he rides. The glint and flash and clang of Excalibur still glorify mortal combat wherever honor and heroism take the field. And medical knighthood, too, is yet prominently abroad in the land, its mold and mien worthy of the finest traditions of the Round Table, all nobly aglow with eagerness for lofty emprise, grandly daring, superbly doing.

Again, no; the medical knight is not "*rara avis in terris*." Chivalrous doctors are many—aye, are in the ascendancy. But in the frenzied hurly-burly of life of the times, the mad chase and race for gain and pleasure, one runs the risk of losing his landmarks. It is well to frequently orient. Par-

ticularly apposite is it to take cognizance of the insidious dangers of apostasy and decadency peculiar to the hour. A man should be his own sternest, most exacting, most inflexible critic and judge, not hesitating to dissect to the very core his propensities, his motives, his purposes, his acts. This the true knight of medicine will not fail to do.

Enticements, the lulling lures of Siren song, and snares and labyrinths in whose recesses lurk Minotaurs, and gulf, Charybdes relentless and insatiable, of the potential baleful effects of all these upon medical knighthood let us first note some involving more imminent hazard to the doctor as to his personal character. A risk immediately evident is that, in the cold, leaden atmosphere of stolid realism, he may lose his ideals. Sentiment is considerably out of vogue—if not *passé*, at least is not the wear. But sneer as you will, it is nevertheless sentiment principally that makes life worth while and the world beautiful. And sentiment is the substance of idealism. And ideals are the stars of life. Though we can not reach the stars, yet by them we should sail. Let the knight of medicine remain a sentimentalist and an idealist.

Another present peril to the doctor is that, in the mad rush and crush for emoluments, he may lapse into venality and servility—may renounce his liberty for a price—may sell his birthright for a mess of pottage. In anxiously, distractedly providing for and safeguarding our existence, we are prone to overlook and neglect our life. Would you maintain your self-trust, your self-poise, your self-peace, your self-respect, your self-approbation? Think as a freeman and act as the single and independent captain of your soul. And those elements of character are never failing sources of higher living, from which flow benefits and blessings manifold.

In the entangling web of fashion, of flattery, of false devotions, our medical knight finds it hard to keep his shield bright and his sword keen—hard to stand by conviction and to champion principle. The doctor is a brave man—cowardice, in the common sense of the term, is no vice of his. But the bravest of the brave were Themistocles, Coriolanus and Benedict Arnold. Ordinary bravery is on a level far below that of truest courage. Let the doctor aspire to the supreme courage which means self-mastery—which is the power to compel one's self to strike his mightiest blow for truth and right as he sees truth and right.

Seemingly all the world is in riotous pursuit of luxurious ease and prodigal pleasure; and, lest he beware, our knight will be caught in the surging throng. Let him remember that a castle of indolence is dear at any price—is a curse to its lord. Let him be assured that the fullest consciousness of dignity and worth can be gained only in the midst of toil and struggle—that his proudest heart-throbs will be felt as he plunges into the *mêlée*. What a real man finally will place the greatest value upon, and most exult in, is hardships endured and duty done.

How easy it is to be drawn into the whirl and swirl of to-day's vast maelstrom of corruption! Let the medical knight ever bear in mind that no bad man can be a good doctor—a criterion absolute. Forever a gem of utterance will be Hippocrates' reference to the true physician as "an upright man

skilled in the art of healing." Of the immortal Coan himself Renouard says "*Ce fut autant par ses vertus que par son génie q' Hippocrate mérita les suffrages universels.*"

In this age of polytechnics the trend of thought and activity is toward the exclusively mechanical. So there is a serious chance that the doctor may shrink into a mere technician. But, by reason of the nature of the material wrought upon, the symmetrically constituted physician of genuine type can not be essentially a craftsman. The worker on inorganic matter a mechanic, yes—the same even of him who deals with those organic forms not self-known nor self-ordered, insentient vegetable structures and instinct-subservient animal existences. But he who works on man operates in a domain beyond and above exact and rigid mechanics. Considering man's relative littleness as a part of the universe, Pascal exclaims "*Je ne vois que des infinités de toutes parts, qui m'enferment comme un atome, et comme une ombre qui ne dure qu'un instant sans retour.*" Again contemplating man in his majesty as a thinker, he more sanguinely says, "*L'homme n'est qu'un roseau, le plus faible de la nature, mais c'est un roseau pensant.*" And by that token, this little creature, man, standing on his diminutive home-planet, may shout out to the stately stars, Richelieu's shining sibyls, I am greater than you all! And this mind-endowed organism, at once insignificant and sublime, constitutes the doctor's problem. The whole of man is within his rightful realm—every part of this being he must touch, every chord of this nature he must try. The worker with the task thus implied only and straitly a technician? No; an *artist* is he ever, the artist paramount.

As to the medical knight's intercourse with his fellow-knight, it may be asserted that strong to-day is the temptation to lower in this regard the standards of chivalry. It must be confessed that not a few are recreant to our nobler traditions of intra-professional honor, generosity, courtesy. Transgression is the easier because duty in this direction is so difficult of definition—can not be adequately expressed in rules and precepts. Just what specifically to do in the varying shades of circumstance may not, indeed, be unexceptionally formulated; yet the proper spirit of conduct can be plainly indicated and more plainly felt. And after all, the spirit is the main thing. Upon this point the whole question principally pivots. Some of the most flagrant offenders against the knightly spirit are cautious that their actions be literally and technically correct—like the promoter of dubious enterprises who, when he was about to launch a new project, would anxiously ask his lawyer, "Can they put me in jail for it?" If we desire and aim to be chivalric we shall not far fail of gentle respect and consideration for each other, ethical code or no ethical code.

Charlatanry apparently pays so well in dollars that to the medical knight the tempter whispers, Assume the impostor's guise, and adopt his methods, to an extent that will not much wound dignity and honor, and yet will effect a successful rivalry. But let him pause to consider that to secure any advantage over the Hun with his own weapon of gas it was necessary to out-Hun the Hun. The very

thought of out-quacking the quack!—it is worse than tartar-emetic. And then this covertly suggested policy of balancing, vacillating, *wabbling* between professionalism and commercialism reminds one of the boy who, with the same spoon dipped alternately in a dish of apple-butter and another of smear-case, until he had them both so mixed that he could not tell which was apple-butter and which smear-case.

But, really, such discussion is irrelevant as concerns the true knight of medicine. He will not in any way compromise with charlatanry—"and that's the end on't." He knows that to sell himself at all would be to sell himself into bondage. Dearer than life to him are his manhood and knighthood—he would not give them up for the earth and the moon and the sun and, as good measure, the morning star. Any doctor that could be bought, were he a diagnostician like Apollo, and a therapist like Apollo's son Aesculapius, and a surgeon like Aesculapius' sons Machaon and Podalirius, still would he be a dastard and a renegade. And the medical knight need have no misgivings regarding the result of his adherence to principle. The able president of one of our gigantic life insurance companies a few years ago said that it is idle to think of conducting life insurance successfully without the cooperation of the best doctors of the country. So elsewhere and everywhere, to the doctor that rings true will not be lacking distinction and honorarium. Indeed, humanity could but very poorly get along without the old-fashioned, the classical, the Hippocratic doctor, the medical knight. His place and his fame are secure against the tooth of time.

That magic name Hippocrates!—it is one to conjure with. At its mention, as by enchantment how before us pass visions of all that is fine and precious and noble and glorious in the kingdom of medicine! Hippocrates, associate and peer of the lustrous intellects grouped around Pericles, alike insusceptible to theurgic charlatanry and Persian gold, prince and paragon of doctors, let him while run the sands of time be lawgiver of the healing art. And so will our banners be ever advanced, never set back. And so a follower in the footsteps of the Sage of Cos will blamelessly pursue his career, a white-plumed knight who will have no occasion to voice the lament of Shakespeare's young Henry—

"For my part, I speak it to my shame,
I have a truant been to chivalry."

To us doctors first of all has our own fair-famed John McCrae "from failing hands thrown the torch." Ours be it unflatteringly to "hold it high," and bear it on. And at the end may each have won clear title to the legend of the pure-hearted, the great-souled Bayard, "*Chevalier sans peur et sans reproche.*"

Priority of Italy in Animal Vaccination.—In one of the anniversary addresses given on the occasion of the centennial of the foundation of the French Academy of Medicine, it is stated that in 1864 Depaul by his condemnation of human vaccination was responsible for the introduction of calf lymph. It is admitted that the first calf used came

from Naples. Torraca in *La Riforma Medica* for January 22, 1921, xxxvii, 4, states that Depaul and Lanoix, to be mentioned later, are entitled to the full credit for introduction of animal lymph in France, but that Galbiati of Naples was the first to establish the superiority of this method. This innovation goes back to the year 1810, when the physician mentioned was attached to the Hospital for Incurables. He declared against arm-to-arm methods chiefly because of the danger of communicating syphilis.

In 1857 another Italian, Palasciano of Naples, attended an International Medical Congress at Lyons, and called the attention of the members to the frequency of vaccinal syphilis and to the preferable employment of animal lymph in vaccination which had been used in Naples for many years. His remarks were warmly received. It was then decided to send the young Frenchman, Lanoix, to Naples to learn the method of animal lymph vaccination from Negri, the successor of Galbiati. This method was spoken of at the time as the "Neapolitan method." Lenoix having returned to France with an inoculated heifer, Palasciano telegraphed his Lyons colleagues to that effect. Shortly after, the first inoculation with animal lymph was made in France.

Prosecutions for Bestiality in the XVI and XVII Centuries.—An article on this subject appears in the Bulletin of *Le Progrès Médical*, October 30, 1920, xlviii, 44. In antiquity Venus was believed to wreak vengeance on the perpetrators of this crime. On the other hand it was sometimes assumed that the gods visited mortals under the appearance of animals. The offense therefore differed with the sex of the culprit. The use of she-asses and she-goats also entered into religious rites which readily degenerated into orgies. This led among the Hebrews to the condemnation to death of man and animal at the same time. This law eventually became incorporated into both Roman and German statutes which were in full vigor up to the XVII century throughout Europe. Nevertheless offences were not uncommon and in a book by Hernandez entitled *Bibliothèque des Curieux*, forty prosecutions during the XVI and XVII centuries are narrated. The culprits comprised some feeble-minded individuals while others had been disappointed in love. But the evidence was often very weak and supplied by neglected women or envious neighbors. The culprit apparently was not detected in the act itself but was accused of merely suspicious behavior. If the evidence was defective the accused might at times be put to the torture.

No one once accused was ever allowed to escape death, which was usually by hanging or strangulation, the corpse together with the accused animal being thrown into the fire and the ashes scattered to the winds. Eventually there was a reaction against these prosecutions which perhaps culminated in the pardon by Frederic the Great of a subject convicted of bestiality. The memorandum of the king on the document, which doubtless still exists, refers to "liberty of conscience in free states." Such an extreme view never gained acceptance and the modern attitude is a compromise between the two views.

WHAT ABOUT A CURE OR PREVENTIVE OF TUBERCULOSIS?*

By STEPHEN J. MAHER, M.D.,

NEW HAVEN, CONN.

CHAIRMAN OF THE CONNECTICUT STATE TUBERCULOSIS COMMISSION.

As perhaps you all know, the members of the staffs of the various State Tuberculosis Sanatoria hold a medical conference once a month at one or other of the sanatoria. We held one on Monday last at the Norwich Sanatorium. The December meeting was at the Shelton Sanatorium. The Superintendent of Shelton, Dr. Lynch, and myself had just returned from a couple of tuberculosis meetings in Europe. At this Shelton conference, Dr. Lynch read a paper, comparing Connecticut sanatoria with the new English sanatoria, and I read the paper that I am about to inflict on you. I give this prefatory explanation in order that you may make allowance for whatever difficulties of slant or verbiage you may discover in my paper. Remember that it was written for a group of doctors who are doing research work in tuberculosis and who are hoping that they themselves, or some Connecticut physician or physicians, will forge the key to the great mystery of tuberculosis. I don't mean to insinuate that you may not be as enthusiastic and as hopeful as they. I know you would be if you lived among the tuberculous as they do, and had at your command the laboratory facilities that they have.

The leaders of medical thought in England and France are wide awake to the new situation created by the war, and there is everywhere evidence in European universities, hospitals and laboratories, and meetings, that a great medical inventory is going on, a great effort at separating the medical chaff from the medical wheat, a great desire to participate in the epochal discoveries that are apparently imminent at this time.

In no branch of medicine is the atmosphere more surcharged with this electricity of independence and expectation than in the branch in which we are especially interested, the branch of tuberculosis. In this branch there is an evident discarding of many textbook and propaganda theories, but there is a distinct clumping of research workers about the tubercle bacillus. This, of course, is a recognition of the wisdom of the advice that Koch, shortly before his death, gave to his collaborators in Berlin—the advice to concentrate their re-

searches on the tubercle bacillus. It is probable that the chief topic of discussion at the International Tuberculosis Conference, to be held next summer or fall in London, will be simply "The Tubercle Bacillus."

In order, therefore, that we in Connecticut may keep step with the leaders of the coming years and that we may be able, perhaps, to add something of value to the world's treasury of medical truth, and that I may give an intelligible answer to the question raised by the title of this paper, it would seem that today you ought to let me focus your attention on the tubercle bacillus.

You may tell me that we have all been doing some hard thinking about the tubercle bacillus for many years, and that the attention we have given to that malignant microscopic vegetable hasn't done us or anyone else much good. Well, perhaps so; but "dogged does it." Bear with me for a while. It is possible that I may be able to recall some phase of the subject that we had forgotten and that, if we had remembered it, would have given us a foundation for some of the brilliant research work for which the world is now so hungry.

Let us take first the avian form of the tubercle bacillus. What do we remember about it? Anything besides the facts that it looks like the human tubercle bacillus; that it kills fowl; and that it grows best at a slightly higher temperature than either the human or bovine forms? Did we know that it also kills pigeons, pheasants, peacocks, guinea hens, crows, turkeys, swans, canaries, sparrows, finches, parrots, and in zoological gardens such captives as vultures, ostriches, herons, seagulls, and eagles? Did we know that ducks and geese are almost immune to tuberculosis? Did we know that polar birds, like the Arctic swans, when they fly south and are captured in warmer climates, promptly die of avian tuberculosis? Did we remember that in birds, the lung, the pleura, the pericardium, and the kidneys are seldom attacked with tuberculosis, and that the most severe manifestations of the disease are in the abdominal viscera and on the skin, claws, and beaks? Did we know that of 154 parrots examined by the veterinarians of Berlin, 56 were found to be tuberculous?

Have we made a note of the fact that parrots and canaries are sometimes rendered tuberculous by the human type of the tubercle bacillus, and that other kinds of birds, especially the barnyard varieties, are practically immune to the human type of the tubercle bacillus? Do we remember the violent but interesting clashing of opinions as to whether human or bovine tubercle bacilli can be made, by prolonged or repeated passage through birds, to take on the characters of avian tubercle bacilli?

*A paper read before the New Haven Medical Association, January 5, 1921, and the New London County (Conn.) Medical Society, April 7, 1921.

Do we remember the beautiful affirmative experiments of Von Behring, Nocard, Bang, Wiener, and Bongert, and the negative results of some of the other disputants, notably Zwick and Zeller? You may have remembered all these things about the avian tubercle bacillus. I had forgotten some of them, and some that I can now see invite research. Let us peer a little further into the darkness that surrounds the avian tubercle bacillus.

Can the avian tubercle bacillus cause tuberculosis in man or other mammals? Until recently the answer to that question would have been in the negative. Now, however, we learn that bacilli of the avian type occasionally have been found in the spontaneous tuberculosis of white mice, rats, rabbits, hogs, monkeys, horses, and cattle, and by a very few investigators in the tuberculous glands, kidneys, and skin of human beings, usually children. One investigator, Lowenstein, who reports three cases of avian tuberculosis in children, furnishes an interesting argument in favor of hard-boiled eggs. He ascribes the infection of his little patients with avian tubercle bacilli to their eating of raw or almost raw hens' eggs.

Yet, strange as it may seem, it is very difficult to induce tuberculosis in the guinea pig with avian tubercle bacilli. The usual proof that a certain strain is avian, not human, is that it causes prompt general tuberculosis in an injected fowl and no tuberculosis or almost no tuberculosis in a guinea pig. An injection into a rabbit also would help in the diagnosis. The avian type causes immediate tuberculosis in the rabbit. If the injection into a rabbit be made intravenously, even of a very small dose of avian tubercle bacilli, the germs multiply in the most astonishing way in all the organs of the body and kill the animal with what is known as Yersin's septicemia. The horse injected intravenously with avian tubercle bacilli dies soon of general tuberculosis. While the cow, although not immune to repeated meals of avian tubercle bacilli, shows a much greater resistance than the horse.

Now, what ought we to bear in mind concerning tuberculins made from avian tubercle bacilli? They are a little weaker than human or bovine tuberculins. They may be used instead of the autogenous types in men and cows. They cause characteristic reactions in tuberculous men, cows, and birds. Positive reactions in fowl are positive proof of tuberculosis. They do not cause reactions in the last days of the tuberculous fowl. They have much less reactive power on fowls than human and bovine tuberculins have on men and cows. They must be injected in doses of two or three cubic centigrams to cause the death of a tuberculous fowl; that is, about 300 to 400 times as much as the dose of human tuberculins needed to kill a tuberculous guinea pig.

And as to the problem of the human and bovine types of the tubercle bacillus! Don't be frightened; I am not going into the philosophic question of whether there are two or more types of tubercle bacilli, or whether, as Calmette claims, there is but one type, and that that type takes on varying characteristics in varying environment. Personally, I reject the explanation of both the Koch and the Calmette schools. But that is another story.

For the practical purpose that we have in mind today, that is, the seeking of clues that may lead us to some important research work during the coming year or two, it is enough to recognize what everybody now admits, that the tubercle bacillus found in the ordinary tuberculous cow differs in many important ways from the tubercle bacillus found in the ordinary case of tuberculosis of the lungs of human beings.

The more important of the recently accepted differences between the bovine tubercle bacillus and the human tubercle bacillus may be stated as follows:

The first generations of human tubercle bacilli grow better on glycerinated egg media than on non-glycerinated egg media; the bovine tubercle bacillus, fresh from the animal, grows with difficulty or not at all on glycerinated egg media; but luxuriantly on non-glycerinated media. Both the human and the bovine types cause generalized tuberculosis in the guinea pig, but the human type has little or no power to infect the rabbit, while the bovine type, in the very smallest doses, causes a quickly generalized tuberculosis in the rabbit. In tubes of glycerin potato to which a little human bile has been added before sterilizing, human tubercle bacilli will grow quickly, and luxuriantly, while bovine tubercle bacilli will grow only very slowly and scantily; on the other hand, if beef bile be poured into glycerin potato tubes, the human tubercle bacilli will vegetate only with the greatest difficulty, while the bovine type will grow abundantly. White mice are quickly tubercularized by the bovine type and slowly or not at all by the human type. Rats, on the contrary, resist the bovine strains, but they are very susceptible to the human strains. If on the shaved skin of guinea pigs, tubercle bacilli or tuberculous material of the two types be rubbed, the bovine type will cause a quick development of general tuberculosis, whereas, the human type will produce a very slow and small infection or none at all. If into the milk ducts of various goats, in their milking time, the two types of tubercle bacilli be injected without hurting the mammary glands themselves, the bovine type will cause a general tuberculosis and kill the animal, whereas the human type will cause only a local abscess that will slowly contract and may swell up again at the next period of lactation, but will never cause general tuberculosis. If fifty milligrams of bovine tubercle bacilli be injected under the skin of the shoulder of a cow, the animal will become rapidly and fatally infected with tuberculosis; if fifty milligrams of human tubercle bacilli be injected under the skin of a cow, only a local abscess will develop.

Can the bovine type of the tubercle bacillus be transmuted into the human type, and can the human type be transmuted into the bovine type? This is one of the big problems of the day. At the great International Tuberculosis Congress in Paris in 1905 and in Washington in 1908, a loud "No" was the almost unanimous answer from the assembled savants. If today the question were put to the men who hold the torches in the great quest for the truth about tuberculosis, most of the answers would probably be "No," but the "Nos" would be comparatively feeble and hesitant, and there would be many a vociferous "Yes."

For instance, Von Behring, Romer and Ruffel and Damman, and Mussemeier and Jongh claim that strains of human tubercle bacilli isolated from human tuberculous sputum became, after six months' residence in a goat, capable of causing general tuberculosis in cows and even after being injected into a series of three guinea pigs, retained the characteristics of the bovine tubercle bacillus.

In the report of the British Commission is the record of a strain of tubercle bacilli from a human tuberculous knee, that was passed through a series of four calves. The pathogenic power of the strain was only that of the human tubercle bacillus in the first and second calves of the series, but in the third calf it produced tubercles in the liver and spleen and lungs; and in the fourth calf it produced general tuberculosis and caused the death of the animal. Guinea pigs injected with the organs of the first and second and third calves were found to be infected with tubercle bacilli of the human type and non-pathogenic for rabbits, but the guinea pig injected from the fourth calf was infected with tubercle bacilli of the bovine type which were very pathogenic for rabbits.

Eber of Leipzig reported in 1913 that with the tuberculous spleen of guinea pigs, containing proven human tubercle bacilli from sputum, he had infected intraperitoneally a series of calves and had recovered from the tuberculous abdominal glands of these calves strains of tubercle bacilli that possessed all the required characteristics of bovine tubercle bacilli. Park-Krumwiede and O. Malm have made somewhat similar reports.

It seems to me that this attempted résumé of mine would not be complete, at least it would not have the stimulating effect that I hope for, if I did not say a few words about some of the attempts that have been made to cure or prevent tuberculosis by using vaccines and sera and live tubercle bacilli.

As to tuberculins of all kinds, it is pretty generally agreed that, whereas they are of great value as diagnostic agents, they are practically of no value as curative or preventive agents. And this statement applies to tuberculins of all kinds. Of course tuberculin has taught us much about tuberculosis, and the reaction between the seed and the soil in this disease. And it still puzzles us somewhat, but it is no longer to be considered as possibly the specific that we seek for cure or prevention.

And the same cheerless verdict must be given on all the painstaking efforts in the laboratories of the world to produce a serum for tuberculosis analogous to Von Behring's diphtheria antitoxin. They have all failed, no matter whether horses, goats, dogs, sheep, or rabbits were injected with any kind of tuberculin or any kind of tubercle bacilli or any kind of combination of tuberculins and tubercle bacilli. The resulting sera contained antibodies enough and of enough kinds, but they had no appreciable effect on the course of tuberculosis in man or beast. As Calmette's recent book puts it: "Today, it appears that the treatment of tuberculosis by specific sera has not realized our expectations."

The same discouraging result has come from the use of tubercle bacilli, killed by heat or by various chemical agents; tubercle bacilli whose waxy coats had been dissolved by ether or other solvent;

tubercle bacilli bathed or macerated in iodine water, chlorine water, glycerin, urea, and galactose, ovolcithin, formaline or toluol; and tubercle bacilli modified or killed by light.

All these failures bring us to the last chapter, the chapter of the present hour, the chapter in which briefly we will consider the use of live tubercle bacilli as a vaccinating or curative agent. Of course such a discussion is dangerous, but we are accustomed to danger.

In 1907 Calmette and Guérin reported that their prolonged attempts at vaccinating cattle against tuberculosis had demonstrated beyond question that tuberculous animals, that is, those that gave a positive tuberculin reaction, were infinitely more resistant to an intravenous injection of bovine tubercle bacilli than were the healthy animals, that is, those that did not react to tuberculin.

This brought to the minds of these investigators and of all who knew of their work the famous phenomenon of Koch which he discovered and described in 1890 and which led him to devise tuberculin, but which in recent years had been thrown into the discard. According to Koch, this is the phenomenon of Koch:

"If we inject into a healthy guinea pig a pure culture of tubercle bacilli, the wound usually closes and seems cured in a few days. From ten to fifteen days later there appears at the point of inoculation a hard nodule which soon opens, and leaves an ulcer that persists until the death of the animal. Guinea pigs already tuberculous for from four to six weeks, react very differently when given a second inoculation of tubercle bacilli. In their cases, no nodule forms at the point of reinoculation, but one or two days later the injected spot becomes hard and then violet red and then black. Finally a tiny necrotic area develops, and sloughs off, leaving a superficial ulcer which heals quickly and thoroughly and without causing thickening of the neighboring glands.

"Therefore, it is plain that tubercle bacilli, when inoculated under the skin of guinea pigs, behave very differently in the healthy and the tuberculous guinea pig. This difference of behavior under these conditions is not confined to live tubercle bacilli. It is true also of tubercle bacilli killed by boiling, or by chemical agents."

Then somebody remembered the law that Marfan had enunciated in 1886, that children apparently cured of an attack of suppurating tuberculous glands of the neck were thereby safely vaccinated against getting any kind of tuberculosis in later life. The new discussions of this so-called law and of the phenomenon of Koch have laid the foundation of most of the new work in France and were in Von Behring's mind when he tried to vaccinate cattle against tuberculosis by injecting into them or feeding to them live human tubercle bacilli. He called his emulsion of human tubercle bacilli bovo-vaccin. Bovo-vaccin failed because: (1) although it conferred a marked power of immunity for several months against infection by doses of pure bovine tubercle bacilli, it gave little or no immunity against the infective power of the tuberculous barn; because (2) it was considered dangerous for human beings to have to do with an animal that was voiding human tubercle bacilli, and because

(3) it would be criminal to use the milk of a bovo-vaccinated cow, for, of course, such milk would contain live human tubercle bacilli.

Among the other interesting attempts to use live tubercle bacilli was the much exploited one of Heyman of Belgium. He used human tubercle bacilli in a permeable capsule. These he inserted under the skin of the cow. The Belgian Government investigated this matter and pronounced the Heyman method a failure.

All the attempts to vaccinate or cure with the tubercle bacilli of cold blooded animals, or with live avian tubercle bacilli, or with sensitized tubercle bacilli, or with tubercle bacilli kept for varying periods in various refractory animals have failed.

Theobald Smith's scheme of vaccinating cattle by injecting intravenously one dose of bovine tubercle bacilli, whose virulence had been somewhat attenuated by age, is not in use because of the necessity of quarantining the animal for months after the treatment, and the fact that the strain was still capable of causing tuberculosis in guinea pigs.

The scheme of Webb and Williams of this country, ingenious as it was, of injecting with one virulent tubercle bacillus and then gradually increasing the size of the dose, has failed. Proof of benefits were wanting and the danger to the patient and the community were evident.

Of course you know that Calmette has for years been the leader of all who scoff at the theory that tuberculosis of the lungs is an air-borne infection. His contention is that it is practically impossible to infect lungs by inhalation. He insists that infection is usually through the food tract, and that the tubercle bacilli reach the lungs through the blood stream. In considering ways of administering live virus vaccines to animals, he naturally had recourse to the food tract. He and his friends and followers have done much interesting work along this line. They have concluded (a) that the immunity conferred by the administering of live tubercle bacilli lasts only while these vaccinating germs remain alive in the animal, and that (b) in order to succeed in thoroughly vaccinating against tuberculosis, there must be secured, instead of the virulent human or bovine tubercle bacillus, capable of forming tubercles, a tubercle bacillus which will be virulent but will not have the power of forming tubercles, a tubercle bacillus that will be tolerated by the lymphatic system and that will, for a long time at least, be able to resist the destructive power of the phagocytes; (c) calves and young cows and oxen are easily immunized, even against the infective power of tuberculous barns, by the administration by the mouth of certain live bovine tubercle bacilli of weakened virulence.

Two weeks ago there appeared in some of the more important papers of the country a despatch from Paris to the effect that Calmette and the other workers of the Pasteur Institute had not only announced that they had perfected an antituberculosis vaccine for cattle, but that concerning human tuberculosis, Calmette had said: "We've got results, but to realize a cure for man still demands long experiment. But, at least, we are certain that our living bovine bacilli are harmless to man, even when inoculated in his veins in a dose of 44,000 bacilli."

What did Calmette mean by this? The explana-

tion appears in the last pages of his new book. He has found, he thinks a means of securing the long-sought virulent, but non-tubercle-producing tubercle bacillus. He grows virulent tubercle bacilli on glycerin bile potato instead of on glycerin broth potato, and after seventy subcultures on this medium, he obtains a strain that has lost its power to produce tubercles, but has retained its power to resist phagocytosis. This strain, before it was subjected to the detoxicating effect of the cultivation in glycerinized bile, caused a fatal tuberculosis in a cow in four weeks with an intravenous dose of three milligrams; whereas, after treatment with bile, the enormous intravenous dose of 100 milligrams of the culture caused in a cow only a sickness resembling typhoid fever, from which the animal recovered in fifteen days. At autopsy, these animals showed no signs of tuberculosis. When the vaccinating dose of three to five milligrams of the bile-treated bacilli was injected intravenously twice, at a month interval, into cows, and when later three milligrams of the virulent untreated bacilli was injected intravenously into these same cows, the cows remained perfectly well; and when autopsied eighteen months later, showed no signs whatever of tuberculosis in any organ of the body. Nevertheless, when the apparently healthy mediastinal glands and the tracheal glands of these cows were ground up and injected into guinea pigs there was a development of tuberculosis in a few of the guinea pigs. Not at all dismayed by this finding, Calmette says that is what he hoped to find as proof of the value of his bile-treated bovine tubercle bacilli.

"See," he says, "these virulent tubercle bacilli that caused tuberculosis in the guinea pigs after eighteen months in the cows, would have caused tuberculosis in the cows if the cows had not received the immunity conferred by the bile-treated tubercle bacilli."

I have purposely not considered the so-called fourth class of tubercle bacilli, the tubercle bacilli of fish or cold-blooded animals. Nor have I included here a discussion of the non-pathogenic acid-fast bacilli, the so-called pseudo-tubercle bacilli. Both of these classes are to me of great interest and on my studies of them I have written considerably; but I do not think it fair to try to impress my heretical views on this conference. At this conference, I would merely report as the result of my recent discussions of the subject with many of the English and French leaders, and as the result of my reading of much of the recent English and French literature; (1) that there is a spreading conviction that we will not make much further progress in the fight against tuberculosis until we have obtained a specific treatment for its cure or prevention, or both; (2) that in all probability, this specific, when found, will be some live relation or modification of the tubercle bacillus; (3) that the reason this specific has not been found before this late day is that we have not known and do not now know the tubercle bacillus; and (4) that it behooves all the capable and ambitious who are engaged in tuberculosis work to study the tubercle bacillus, and to keep themselves informed of the studies of the tubercle bacillus made by their fellow workers in this and other lands.

A CLINICAL STUDY OF TUBERCULOSIS IN CHILDREN.*

By ABRAHAM LEVINSON, M.D.,

CHICAGO, ILL.

ATTENDING PHYSICIAN CONTAGIOUS DEPARTMENT, COOK COUNTY HOSPITAL, CHICAGO; ASSOCIATE PEDIATRICIAN SARAH MORRIS HOSPITAL, CHICAGO; CHIEF OF THE "CONTACT TUBERCULOSIS" CLINIC, MICHAEL REESE DISPENSARY.

THE present study was made at the Children's Tuberculosis clinic of the Michael Reese Dispensary, Chicago. The purpose of the clinic was to follow-up the children of tuberculous parents. There were many cases, however, that had no contact history but were referred to the clinic because they showed symptoms suspicious of tuberculosis. Altogether 300 children varying between the ages of 2 to 16 years were observed. Of these 141 cases were diagnosed as positive, 83 as negative tuberculosis, and 76 cases are still pending a diagnosis.

The diagnosis of tuberculosis was made both upon the clinical manifestations, subjective as well as objective, and upon the tuberculin tests. No matter how few the clinical manifestations, a patient was considered tuberculous if he reacted positively to one of the tuberculin tests. On the other hand, a patient that gave no tuberculin reaction was considered negative or only suspicious even if he presented some suspicious findings.

As a basis of classification for the positive cases, I took the following: Acute miliary tuberculosis; Acute or chronic active tuberculosis; Latent tuberculosis. All cases presenting symptoms of tuberculous meningitis or miliary tubercles on x-ray examination are classed as miliary tuberculosis.

Cases that present pulmonary tuberculosis in acute or chronic form, pleurisy, caseous cervical adenitis with or without a discharging sinus, tuberculous glands anywhere else in the body, tuberculous peritonitis, tuberculous kidney, or psoas abscess are classed as active tuberculosis.

Children who give no symptoms enumerated above but show a positive tuberculin test are grouped under latent tuberculosis. The question arose where to class bronchial gland tuberculosis, that is: Children who show dullness over the hilus, a positive D'Espine sign, and a hilus shadow on x-ray examination. I have decided arbitrarily to class this type of cases as latent tuberculosis, for, as will be seen later, these children show very few, if any subjective symptoms.

sented symptoms and signs of active tuberculosis, and 128 were grouped under latent tuberculosis. It was natural not to have had any cases of miliary tuberculosis, as the work was done in the dispensary and patients with miliary tuberculosis either go to a hospital or stay home.

Of those who were classed as actively tuberculous, 3 had acute pulmonary tuberculosis; of these three, one patient was 10 years old, one 11 years, and one, 12 years of age. All three of them coughed, lost in weight, and ran an afternoon elevation of temperature; the lungs showed apical dullness and crackling rales; the x-ray showed a mottling over both apices.

Six cases had broken down cervical adenitis. In all of them, the adenitis was rather chronic, lasting several months, the skin presented a bluish red appearance, was not tender, nor was it as tense as in the acute adenitis caused by ordinary pus organism. Three of the cases resulted in sinus formation. I should like to emphasize that I classified only caseous cervical adenitis under active tuberculosis. Mere palpable cervical glands, although present in many children that have a tuberculous infection spoken of by some French authors as micropolyadenopathy, should not be classified as active tuberculosis as they are not necessarily tuberculous in origin. It is a well known fact that children with decayed teeth or repeatedly infected tonsils gave rise to palpable cervical glands.

One patient had a tuberculous gland in the pectoral region. This case presented a great deal of difficulty in diagnosis as the patient also had an enlargement of the cervical glands and was very anemic. Syphilis and Hodgkins' disease came up for consideration. The Wassermann test, however, was negative and the blood showed no findings characteristic of Hodgkins' disease. The final diagnosis was made by dissecting the gland in the pectoral region and finding a caseous tubercle in it. One patient had a psoas abscess which conformed to the classical description of this condition.

The patient who presented tuberculosis of the kidney, showed tubercle bacilli in the urine and had previously been operated upon for an epididymitis.

Phlyctenular conjunctivitis was hard to classify as there is a great diversity of opinion in the literature regarding the nature of this condition. I have, however, classified the two cases as active tuberculosis, because of the positive von Pirquet, the

Table 1, Distribution of 300 cases studied at the Michael Reese Dispensary, Children's Tuberculosis clinic.

Distribution of Cases.—Out of the 141 positive cases that came under my observation, none presented symptoms of miliary tuberculosis, 13 pre-

active eye symptoms, and the family history.

*Part of symposium on Tuberculosis in Children, read before a joint meeting of the Chicago Medical Society and the Chicago Pediatric Society, November 17, 1920.

With the exception of the 14 cases described above, the patients at the clinic were classified as latent tuberculosis. This gave a total of 128 latent cases compared to 83 cases that gave a negative von Pirquet. It should be stated that no case

which had come in contact with a tuberculous person was considered negative until 3 Pirquet tests were done at an interval of 2 or 3 months.

Latent Tuberculosis.—In studying the cases classified as latent tuberculosis I wanted to determine how many children with a positive tuberculin test came into contact with an open or closed case of tuberculosis, and whether it was the father, mother, or some other member of the family that had the disease. I was also interested in finding out whether any weight could be attached to minor objective symptoms such as long eyelashes, visible veins of the chest, shape of the thorax, and curvature of the spine. Among the physical signs, I was interested in determining what weight one could place on the D'Espine sign (whispered bronchophony), Eustace-Smith sign (hum over aortic region), the presence of hilus dullness, and in the comparison of the percussion and auscultation findings with the x-ray. In order to keep a record of these observations, I used the following printed outline in my clinic.

the mother too was frequently the source of infection. (Table 2.) This is in variance with the claim so frequently made in foreign literature that the infection is most frequently conveyed to children through milk from tuberculous cows. Of course, in this country the testing of cows for tuberculin and the practice of boiling the milk have done a great deal to minimize the importance of milk as a factor in tuberculosis of childhood.

An inquiry into the previous diseases of our patients showed that most of the children had had measles and whooping cough. About 50 per cent. of them had had epidemic influenza. Whether or not the latter had any influence upon the enlargement of the bronchial glands or upon the tuberculin test is a matter of conjecture. I am inclined to think that influenza played no rôle whatsoever.

Ninety-eight per cent. of our patients had no subjective symptoms; they did not cough, nor sneeze, nor did they run an elevated temperature. Two per cent. of our patients complained of weakness and tired feeling. Sweating was present in 8 per cent. I do not believe, however, that the sweating had any connection with the tuberculous infection.

The children as a whole were anemic and over 90 per cent. were from 4 to 8 per cent. underweight (we followed the table of weights and heights prepared by Boas, Burk, Bowditch, and Smedley); 3 per cent. were above weight.

Eighty per cent. of the children presented visible veins over the chest, most of them over the upper part of the chest; some of them also over the lower portion of the chest, and occasionally one showed enlarged veins also over the upper part of the abdomen. Two cases presented what were suspected as tuberculides. Ten cases showed keloid vaccination scars; otherwise the skin presented no peculiarities.

Ninety-five per cent. of the children that gave a positive tuberculin test had long eyelashes. I did not, however, count the eyelashes as a tuberculous trait, as most of them were brunettes and as such possess long eyelashes as a constitutional feature.

The teeth in most of our children showed some defects, although as the clinic grew the children's teeth improved because of the cooperation of the dentist, nurses, and the patients' parents.

The tonsils were enlarged in most cases. I see, however, no special connection between the tonsils and tuberculous infection. I believe with most people that the primary tuberculous focus is usually located somewhere in the lungs and produces as one of the results enlarged bronchial glands.

Results.—The results of the study were interesting from several points of view. I found that the majority of the children who reacted to tuberculin had come into contact with an open or closed case of tuberculosis at some time or other. In most cases the offending party was the father, although

Although of no special significance in the study of tuberculosis it is interesting to note that 60 per cent of our female children and 30 per cent. of our male children presented a large thyroid. There is possibly a connection between the early maturity of the average child in my clinic and the frequency of enlarged thyroid.

The shape of the chest in most of the children at the clinic was significant. As a rule it was flattened but occasionally it was barrel shaped, especially in the cases that had frequent attacks of asthmatic bronchitis.

Palpation of the chest was negative in all of our patients. Percussion and auscultation, however, showed interesting changes. I have been able to make out decreased resonance over the hilus in 75 per cent. of our cases. Of course the percussion has to be very light, but I believe that one does not have to stretch his imagination to detect decreased resonance in many cases of bronchial gland tuberculosis. Most of the decreased resonance was located in the right prevertebral region corresponding to the lower third of the right scapula. The change in resonance was usually found over an area of two to three inches in length and one to two inches in width. This change in resonance was seldom if ever found in the series of control cases who gave a negative tuberculin test. As will be seen later the x-ray usually confirmed the percussion findings. I therefore believe that hilus dullness is an important finding and together with a positive tuberculin test points to the presence of bronchial gland tuberculosis. No apical dullness was found in any of the cases of latent tuberculosis.

Percussion showed no change in the heart boundaries unless there was an accompanying endocarditis.

The auscultatory change that was rather constant in the cases that presented dullness over the hilus was whispered bronchophony over the vertebral region. I found that all control cases had whispered bronchophony down to the fourth dorsal vertebra. I therefore consider that as the normal limit. The cases of positive tuberculin tests and positive x-ray findings usually had whispered bronchophony down to the sixth or the seventh dorsal vertebra. I therefore consider this sign, described by D'Espine, as corroborative evidence of the existence of enlarged bronchial glands. I have noticed that the whispering must not be too low; otherwise the bronchophony cannot be made out.

I found the Eustace-Smith sign (hum over the aortic region) present in only 5 per cent. of our cases. Besides that, I experienced a great deal of difficulty in deciding as to what is positive and what is negative in regard to this sign.

There were no alterations in the heart tones nor were there any murmurs in our cases except when there was an accompaniment of an endocarditis.

The abdomen showed no peculiarities, no retraction nor tympany, nor were there any palpable glands either deep or superficial.

Most of the children had a slight lordosis; some also had scoliosis. Whether or not the presence of curvature of the spine had any connection with the latent tuberculous process I am not prepared to say. I am inclined to think, however, that the curvature of the spine was more a result of the

faulty position at school and had nothing to do with the tuberculous infection.

The x-ray examination usually confirmed the percussion findings in that a large shadow was shown at the hilus. As a rule there were also striations running from the hilus toward the apex and base. It must be admitted, however, that it is often hard to decide as to what constitutes a pathological shadow, as many x-ray examinations of the chest show some enlargement of bronchial glands. Furthermore, even when bronchial glands are greatly enlarged, there is still a question as to whether they are tuberculous in origin. All one can say is that a marked shadow over the hilus and a positive tuberculin test strongly suggest that the enlarged glands are tuberculous in origin.

In about 10 per cent. of the cases, I thought I was able to identify by x-ray one calcified spot at the base of the lung which I believed to be the oldest lesion, most likely the primary lesion. Whether this is a far-fetched imagination or not, further study might tell. I found a stereopticon plate of greater value than a single plate. The latter, however, also gives valuable information.

The fluoroscope showed enlarged glands in a number of cases. It also gave an indication to the mobility of the diaphragm. As a rule, however, I did not find the fluoroscopic examination of as much value as the radiograph.

The tuberculin tests mentioned in the beginning of the paper have assisted me in establishing a diagnosis of latent tuberculosis. It is unfortunate that the value of tuberculin tests has been minimized to such an extent that physicians have frequently been heard to say, "it doesn't mean anything." I believe it means a great deal in establishing the diagnosis of a tuberculous infection somewhere in the body at one time or another. The assertion that 90 per cent. of the population reacts positively to tuberculin does not hold good universally. In the first place, it does not apply to American people, especially to American children. The statistics of Hamburger and von Pirquet in which 80 to 90 per cent. of older children reacted to tuberculin, could not be duplicated in this country by various observers. In my own clinic eighty-three children who were sent to me because of some suspicion of tuberculosis, reacted negatively to tuberculin. In the second place, were it even true that 90 per cent. of the population does react to tuberculin, it would not minimize the importance of the tuberculin tests. It would simply mean that the greater number of the population has been infected, but that the process has been arrested.

My method of using tuberculin has been the Pirquet. I have used this as a standard because it is simple and because the reaction when positive is quite sharp. Every once in a while, when the Pirquet was negative and there was circumstantial evidence that the child was tuberculous, I used the intracutaneous test. As a rule, I found that the two tests checked quite well. The only advantage I see in the intracutaneous method is that it gives a more or less quantitative result with the various dilutions. To a certain degree, however, even the Pirquet test gives an idea of the severity of the reaction; for example, a very marked induration and angry redness would speak for a more severe

infection than a slight induration and erythema. I have not been troubled very much with pseudo-reactions, mainly because I read the Pirquet results after 48 hours, so that if there are any pseudo-reactions, they will have disappeared by that time.

I have studied 40 cases of latent tuberculosis with a view of determining whether or not the blood pressure was diminished in those cases. However, the difficulty in obtaining a normal standard for children of various ages, and, above all, the negative findings in the positive cases as compared with normal children, made it useless to continue the study.

Treatment of Tuberculosis in Children.—For acute miliary tuberculosis there is no treatment. It is always fatal. There are eight or nine cases on record where miliary tuberculosis has ended in recovery. Of these there is one case that seems to be undoubted; that is a specimen of tubercles of the meninges in a brain preserved at the pathological museum of Vienna. In that case the child had a tuberculous meningitis and recovered from it, but years later died from some other disease. The various methods of treatment suggested for acute miliary tuberculosis seem to have no logical foundation. The best thing one can do for a case of miliary tuberculosis is to make the patient as comfortable as possible during the few weeks of his illness, for it hardly lasts any longer than a few weeks, by giving supportive treatment.

Active tuberculosis should be treated by fresh air, general hygiene, and, whenever feasible, treatment should be directed to the affected organ. Tuberculosis of the kidney, for instance, requires operative procedure; tuberculous pleurisy requires repeated thoracentesis; pulmonary tuberculosis has to be treated by general hygienic measures.

Latent tuberculosis requires no treatment if the patient is doing well. I believe that if the child lives in good hygienic surroundings, nothing more should be done for it. The prophylaxis of latent tuberculosis, however, is very important. Every child that has come in contact with a case of tuberculosis should be under the care of a physician, should be examined repeatedly, the teeth cared for, the tonsils removed if diseased, and the living conditions regulated. Unless we do something for children of tuberculous parents we are going to have a new generation of tuberculous people. Clinics for children who have tuberculous parents should be held in every city. If there is an open case in the family, that case should be removed from the house and if that is impossible, the child should be removed from the house. I am not in favor of sending children to tuberculosis sanatoria, for I believe it makes mental invalids of them. It is much better to remove the offending party from the house. However, when the open case cannot be removed from home or if living conditions at home are such that the child does not get the proper care, the child with latent tuberculosis should be sent to a sanatorium.

In my clinic I used the following routine for my patients:

1. Routine Examination for New Patients.
2. Previous history.
3. Weight and height.

4. Physical examination.
5. von Pirquet.
6. x-Ray of chest.

Routine Examination for Old Patients.

1. Weight every time patient comes in.
2. Height once in three months.
3. Physical examination.

Routine Treatment of Latent Tuberculosis.

1. Patient referred to Nutrition clinic.
2. General instructions as to food and sleeping.
3. Re-examination every 3 mos. unless otherwise specified.

4. Investigation of home conditions.
5. All other members of the family to be examined.

6. All contact cases with negative von Pirquet should be retained at clinic and examined once in three months. All cases with negative von Pirquet with no history of tuberculosis in the family should be referred back to Pediatric Department.

Summary.—1. In a study of 300 children most of whom came in contact with tuberculous people, 141 cases reacted positively to the von Pirquet test and 83 negatively; 76 cases are still pending a diagnosis.

2. Of the 141 cases that reacted positively to establish a diagnosis of the presence of a tuberculous symptoms of active tuberculosis. In ninety per cent. the infection was only latent. Of the 14 cases of active tuberculosis, only 3 or approximately 3 per cent. of the total had active pulmonary tuberculosis.

3. In most positive cases, the source of infection was the father, although the mother was infected in a good number of cases.

4. Ninety-eight per cent. of the cases with latent tuberculosis showed no subjective symptoms.

5. Ninety per cent. of the cases were underweight, most of them averaging from 4 to 8 per cent. below the standard.

6. Long eyelashes and visible veins over the chest were present in the greatest number of children with latent tuberculosis.

7. Seventy-five per cent. of the positive cases showed hilus dullness and whispered bronchophony to the seventh dorsal vertebra. I believe that these two signs are strongly indicative of bronchial gland tuberculosis.

8. The x-ray plates usually confirmed the hilus dullness by showing a shadow over the hilus and often also one or more calcified spots in the substance of the lungs and radiations toward the apex. Although one is not justified in making a diagnosis of tuberculous glands from the x-ray examination alone, the latter should constitute corroborative evidence of the presence of tuberculous glands.

9. The Eustace-Smith sign was very infrequent in the cases of latent tuberculosis in this series.

10. Tuberculin tests when positive should establish a diagnosis of the presence of the tuberculous infection in children. The classification of the type of infection must be made by the subjective and objective symptoms and by the x-ray findings.

11. Latent tuberculosis requires no active treatment. The patient, however, should be given the benefit of general hygienic measures.

12. All children who have come in contact with

a tuberculous individual should be under observation so as to establish the diagnosis and institute treatment if necessary.

If the home conditions are good, children with latent tuberculosis should be left at home. If the home conditions are poor or if there is an open case of tuberculosis in the family, the children should be sent to a sanatorium.

30 NORTH MICHIGAN BOULEVARD.

THE EXTERMINATION OF MAMMALS.

THEIR ECONOMIC VALUE; AND THEIR GREAT IMPORTANCE TO MAN THROUGH THE STUDY OF THEIR COMPARATIVE ANATOMY

By R. W. SHUFELDT, M.D., C.M.Z.S., Etc.,

WASHINGTON, D. C.

ALL over the world the larger mammalia are now rapidly disappearing, and to this statement those of this country form no exception. Hunters of every imaginable caste, whether inspired by the desire for sport, or whether incited by the greed of gain, or whether killing for the sole purpose of effecting a riddance, are now, with marked dispatch, destroying the elephants, the rhinoceroses and other pachydermata, the whales and their allies, the deer, the giraffes, the *Bovidae*, and all the rest. With the passing of these, a great host of the smaller-sized mammalia are likewise disappearing, such as beavers, sea otters, seals, and many others.

Confining ourselves, however, to this subject as it presents itself to us in the United States, it is quite within the recollection of the present generation what the fate of the American bison has been. Fifty years ago they roamed in untold numbers over the plains of the West, and doubtless there was a time when their range extended to the shores of the Atlantic ocean. To-day there are but a few hundred left, and the majority of those, either in captivity or in the wild state, are more or less under man's dominion. The history of the near extermination of the fur seals and other species is equally familiar to us; and, comparatively speaking, the day is not far distant when they, too, will be practically eliminated. Annihilation of the wapiti is proceeding speedily along similar lines, and it is very probable that in another century there will not be a living representative of the grizzly bear on the face of the globe. Our antelope are sure to go soon, for everything is against them, as they die out very rapidly in captivity. Indeed, there is not a single exception to the rule; and the time will eventually arrive when every mammal, save man, of every description and size in this country—or in the world for the matter of that—will have disappeared.

Of course, among the last to go will be the very smallest and most active rodentia and insectivora—such as the mice and shrews—and such species of bats as are very small in size and more or less nocturnal in habit. But these, too, will eventually disappear, as man reduces the *entire* world to meet his needs, and the surface of the globe becomes densely populated and under the complete dominion of our descendants of the far off future ages to come, whatever form the genus *Homo* may, in that dim, distant time, assume. It is likewise quite within the range of the possible that all the mammals now living in the domestic state may disappear and die out. That

will be a much later chapter in mammalian history, however, and will be greatly influenced by marked improvement and universal application of certain motors, machines, food-stuffs, and materials. Small mammals kept for pets will remain the longest of all, and the cat and its descendants will stand one of the best chances here.

In the extermination of the wild forms of the existing mammalia, man will be, and man always has been, the principal agent above all others and all others combined. Among the main factors in operation at the present time effecting this universal destruction is the rapid increase of the population; the enormous extension that is going on everywhere in the way of roads, and the building of railroads and canals and other public ways throughout the country for passage or for travel. And, above everything else, the increase in use of the automobile. These render the abodes of the larger mammalia—the fastnesses of the mountains and forests and the more remote areas of the plains—more and more accessible to man. Next, we have the marvellous growth of the cities, towns, villages and isolated homesteads and the constant founding of new ones. All this menaces the very existence of ferine animals anywhere; moreover, as the wild mammals—especially the wild fur-bearing and game mammals—fall off in number, the ranks of those who annually destroy them are vastly increased, being recruited through the immense growth of the population of our own species. Not only this, but the marvellous improvement in firearms and other skilled devices employed to destroy wild animals of this class, is having a very telling effect, to say nothing of the increase of the skill on the part of those who use them. The destruction of our forests are having another powerful influence, and this will surely go on notwithstanding all the laws enacted to prevent it. The preserved forests of the very distant future in this country will be the properties of the extremely wealthy. These will secure comparative safety to certain species of mammals—especially those of the chase—for a long time; but the age will eventually come, however, when these, too, will be broken up and eliminated, with a consequent disappearance of the animal life they harbor.

Another factor that is exerting a powerful influence in the matter of the destruction of our game mammals—and one that seems to have been largely overlooked by writers on this subject—is the ever increasing facility to those who hunt and kill them for finding out the places inhabited by them. This is accomplished by telephones and telegraphs, also through men telling each other; but principally through the columns of the mass of publications devoted to outdoor life and sporting news in this and other countries. Any thoughtful person will appreciate the importance of this factor the moment the matter is given a thought. Again, field collectors, who pay especial attention to the collecting of the mammalia, are getting away with their quota, and doing their share toward the extermination of the entire class below man. As the specimens become rarer and rarer, this goes on with greater and greater rapidity and avidity, especially as the number of collectors in the field increase, and the scientific and market value of the specimens is enhanced by their rarity and the demand for them.

Museums all over the world likewise have their influence, and it is remarkable what a number of mammals are required to supply their demands to fill out their collections. Thousands of species are captured to this end; and, as museums and money and means are all on the rapid increase, this factor in the extermination of mammals of all kinds, not including man, is not to be ignored.

Many mammals are continually destroyed in order to meet the demands of the food markets; but this, in the main, takes place only during certain seasons. Nevertheless, its operation is destructive—laws to the contrary. We likewise kill mammals all the time to supply anatomical laboratories and anatomical museums as well as osteological cabinets, all over the civilized world,—various countries often exchanging with, or purchasing from each other. This comparatively small factor likewise jeopardizes their perpetuation and existence. Thousands upon thousands of wild mammals have been slain for their pelts; for their heads (and horns or antlers); for ornaments and trophies, and for similar purposes. As the species become rarer and rarer and their money value increases *pari passu*, this kind of sport and trade is entered into with an ever increasing avidity. How keen it may become can easily be appreciated, when one thinks for a moment what unscrupulous men will do when a buffalo's head has a value of from two hundred to five hundred dollars, and it will not be long before the head of a wapiti and moose will fetch a like sum. The enactment and rigid enforcement of wise laws can, and will, mitigate this source of destruction for a long time to come; but the day will surely arrive, when such laws will become utterly powerless, not to say unnecessary; for, through the operation of other destructive factors already enumerated above, the game mammals will all be within the confines of the game preserves of the immensely wealthy, and all the others will long ago have been exterminated as having been inimical to man's interests.

Many mammals feed on each other, and this reduces in number the species thus consumed; while others are destroyed when forests and prairies burn, or the regions inhabited by them are laid waste through the operations of other natural phenomena, as floods, droughts, and tornadoes.

Enough has been set forth now I think to demonstrate that the fate of all mammals below man in time is sealed. The causes that are producing this certain result are in operation every instant of time that passes, and are continuously increasing in force with astounding rapidity. The complete fulfilment of the end may not be for many centuries yet to come; but the tendency is powerfully along the lines indicated, and it is not at all within the realm of the probable that it will be averted. Four or five thousand years—or even double that number—is as but a day in the past history of the Earth; and it may mean very much less than that, when we come to think how many ages it will require to fill out the term of its existence in the ages to come. Any one who has any conception of what geology teaches us along these lines can appreciate this much.

With man's careless destruction of game and other mammals, there seems, nevertheless, a growing desire in him to study more attentively and closely the life-histories of the various species. In

this list many of the game mammals are included, and with the others they come in for their share of being studied and investigated. Many of these studies are undertaken in the field; the habits of the mammals are observed directly in their native haunts and wilds, and in many biological laboratories researches into their morphology are made. Naturalist-photographers are nowadays vying with each other the world over in their attempts to secure photographic pictures of wild animals in nature, and many of these results are most admirable. They are also photographed under a great many other circumstances, and with marked success, as in galleries erected for the purpose in connection with zoölogical gardens, and in others having no such connection. These pictures have great value; their numbers are now rapidly on the increase and with continued improvement in many particulars, as they are produced by those evincing special skill in their production. A large proportion of these, as has just been intimated, have been secured in zoölogical gardens, so that the obtaining of such animal pictures has come to be one of the most important uses to which a zoölogical garden can be put. In England not a few of such photographs have been taken where game and other animals have been kept on private estates and similar places. Others have been secured in various menageries, and still others by those who have kept animals as pets and for the purposes of private study. In fact, these are the several ways in which mammals are studied in captivity,—that is, in public and private zoölogical gardens; in parks and on private estates; in either permanent or traveling menageries, and as pets by individuals all over the world. To supply these several concerns and parties, many collectors of living animals are constantly in the field, and many animal stores and other emporiums are found in towns and cities.

From a zoölogical point of view, a great deal can be learned about mammals kept in a state of captivity, and to this statement our game mammals form no exception.

Apart from all other sources, the best places to study mammals in captivity are in the case of those species kept in private preserves, or as pets, or in the various zoölogical gardens. In the last-named institutions, we often meet with a great many game mammals living with comparative comfort in a state of captivity, such as the bison; various species of deer, and a great many others belonging to the several orders of the class. It goes without saying that the behavior of these animals in confinement does not agree in all particulars with what these same animals exhibit in a state of nature; yet, at the same time, it does in many respects. The differences presented are very much the same as those seen on the part of a man in and out of jail. The more freedom they have and the greater the latitude, the nearer will their habits agree with those they have in a state of complete freedom. Among the best zoölogical gardens wherein to study game mammals under these circumstances is the one in London at Regent's Park; the gardens in Amsterdam; the Philadelphia zoölogical garden, and the National Zoölogical Park at Washington, D. C.

Game mammals of many species from all parts of the world have, from time to time, been kept—and

kept in excellent condition—in all of these places. In some of them, for many, many years past, they have been studied by hundreds of thoughtful people including naturalists from every quarter of the globe. Innumerable drawings and photographs have been made of them; a library of books have been written about them, often illustrated with the best class of colored figures; and, where specimens have died, our most capable anatomists have studied their anatomy and published admirable memoirs and other works upon their morphology.

Among the habits of mammals which can be studied with distinct advantage in large zoölogical gardens, none has a greater interest for us than their breeding habits, mating, and reproduction. It is the rare exception to be able to make observations upon these when the species are living in the wild state; for, under the most favorable of circumstances, but few mammals in nature will pursue their courtships if they suspect for an instant that their arch-enemy man lies concealed anywhere in the neighborhood.

Within the confines of a large and properly conducted zoölogical garden, however, it is an entirely different matter. Here all the stages, processes, and functions of reproduction may be investigated and studied,—often in the most complete and satisfactory manner; that is, in cases of all such as are there kept confined and will breed. Often, too, opportunities are afforded to observe cases of hybridization, and to study the development and growth of the hybrids produced. This is interesting and frequently important. We may note with great detail any such sexual characters as may make their appearance in either sex during the season of the rut, and in other cases where they are permanently assumed throughout life. Again, occasion presents itself over and over to note the wooing of the males, and the due submission of the females, and this is a subject about which nothing like enough has been written. As a matter of fact, it would be a great advantage to naturalists and scientists generally were the behavior of *all* mammals during the breeding season—including the various modes of the copulation of the sexes—studied as closely and recorded as fully as Henry W. Elliott has done for us in the cases of the seals and walruses in his valuable report on the "Seal Islands of Alaska" (1882). Frequently it is a miserable prudism on the part of many or the fear of criticism, or, what is far worse, the dread of the operation of some baneful and asinine laws that have been enacted in this country, that deters naturalists and others from publishing such observations,—all of which is to be most sincerely deplored and deprecated.

Many are under the impression that it is the male among the mammals that invariably makes the approaches, when he discovers the female to be in heat. This, however, is by no means the case; for, as Elliott has shown, it not infrequently happens on the seal rookeries that the female is obliged to tease her would-be lord and master for a greater or less time before she can induce him to perform his duty toward her. The same holds true with other carnivorous animals, and instances are not far to seek where similar behavior may be noted in the case of our own species. It is important to know of those forms among mammals wherein the male serves two or

more females during the mating season, as distinguished from those wherein he confines his attention to a single spouse, as I believe the case is among certain of the *Felidae*. Some male lions, it is said, are faithful to the lioness they select; while in the case of the bull of the fur-seal he may serve, during the breeding season, a hundred or more females in the course of a month.

Record, or rather comparative records, of the duration of the period of gestation among various mammals are also of great value. As is well known, some species bear but one youngling at a birth,—twins or triplets being with them the exception; while other species may normally have a litter ranging from four to ten or more. Some breed two or three times during the course of a twelvemonth, having a number of young at each birth, while others carry a single fetus in utero for a full year. In captivity we may be able to study closely the nature of various species of marsupials; ascertain the times when their young are born; how long they remain in the marsupium of the mother, and a vast deal of most valuable data. The behavior of the parents toward their young is another phase of mammalian life, which may be advantageously investigated in the case of captive and breeding species. In some species the greatest amount of solicitude is exhibited on the part of both parents for their progeny; while in the case of others the male may menace or even destroy them as soon as they are born,—instances of which frequently occur among rabbits and possibly other mammals.

In some groups the young more or less resemble their parents when they are born; in the case of others they are strikingly different either in color or in markings, and to a greater or less degree in form. With respect to their pelage, the young are often much lighter in color than the mother, in other cases so much darker as to be considered black; while among still others they are spotted or otherwise marked, as with various species of the *Cervidae*. It is interesting to know exactly at what times such spots and markings disappear, and to observe, in the gradual development of any species, when the young come to be fully adult and look like the old ones. Kids of the American Prongbuck Antelope are marked almost exactly like the old ones; but the fawns of the mule deer and other species are spotted, which spots disappear as the specimens become adult.

The exact times for the shedding of the coat in various species can also be observed in the case of mammals kept in a state of captivity; but in this, as in other observations, we must always remember that the animals may or may not, in such periodical changes and habits, be influenced by the effects attending domestication or partial domestication. This likewise applies to the shedding of horns, antlers, and other appendages. Captivity often exerts a peculiar influence on the organs of reproduction, rendering the confined species more or less sterile. This may or may not be accompanied by a loss or partial loss of desire on the part of the sexes; and Caton tells us that in the case of the Prongbuck there "is certainly no want of ardor on the part of the male, and the female is not without inclination to breed, but from some unknown cause the union is not fertile."

The dispositions, mental attributes, and other characteristics of mammals, as exhibited in a state of captivity, may likewise be studied and recorded. Some species are vicious and sullen, and never become friendly with their keepers, nor satisfied with their abnormal surroundings and conditions; others, again, are entirely different, and not only become very deeply attached to those who have them in charge, but decidedly decline to avail themselves of their liberty when it is given to them. Even such a species as the common Harbor seal will become so profoundly attached to its owner that no amount of harshness or attempts to force it to resume its liberty will ever avail, and it will return to its master at all hazards.

Some mammals are largely nocturnal in habit, and in large zoölogical gardens can only be properly studied, in many particulars, by the naturalist during the hours of night. Flying-squirrels, skunks, and other musteline species, as well as bats, are all examples of these. Sometimes such mammals, of the kind mentioned, will remain all day curled up half asleep in some nook or corner, ill disposed to bestir themselves at all during the day; whereas, as soon as twilight approaches and the hours of darkness overshadow the world, when other species betake themselves to rest and repose, they evince a surprising activity and an interest in everything going on about them. Other animals seem to require but very little sleep, or else avail themselves of "cat-naps" during the entire twenty-four hours. Racoons appear to be of this nature, in so far as I have been able to judge from specimens I have had, at various times, in captivity.

Some mammals are teachable to a surprising degree, and are possessed of a high grade of intelligence; others, again, are stupid, vicious, and morose, and no amount of the kindest of handling and instruction will avail anything, even getting them to perform the simplest of acts beyond the habits they normally exhibit. So far as I am aware, no one has ever seen such a thing as a performing sloth or armadillo; yet we frequently are compelled to wonder at the remarkable achievements of other mammals in such directions, especially those that have received instruction at the hands of skilled trainers. Menageries are great places in which to observe such feats in some animals, as for example dogs, cats, lions, elephants, and many others; but for some reason these exhibitions have no attraction for me. Others have, however,—particularly where the teaching has been undertaken by a person of scientific training, and the object has been to demonstrate certain phases in the developmental evolution of the instincts, also of reason and intelligence throughout the animal series including our own species. Many species are available for such purposes, including all the simians, and down through the animal kingdom, even to include such invertebrates as ants and spiders.

There is another class of knowledge that mammals in captivity can furnish us, and that is gained through a careful study of the diseases to which they are subject. A very considerable amount of information has been obtained along such lines already, and no insignificant part of this has proved to be of decided benefit to the science of comparative pathology. Many of the diseases to which animals

are subject are similar in most respects to those which afflict our own species, and so such studies are useful and important, even from a utilitarian point of view. But, in addition to this, we should study them for their own sake,—not only with the view of maintaining the mammalian specimens in confinement in as high a state of health as possible, but it is our duty likewise; for these creatures are in a sense our wards and we their guardians, and, being in our power and keeping, everything should be done that conduces to their comfort and daily welfare. So there is the double incentive, their cost to us on the one hand, and our duty as humanitarians on the other.

Of recent years, zoölogy has been an enormous gainer in another respect from studies of mammals kept in confinement, and this has been through obtaining, by means of photography, an elegant class of illustrations of rare and common forms, wherewith to illustrate zoölogical literature, to be used in all kinds of lectures and educational institutions; to assist naturalists and others in their studies, and for other purposes. There are individuals, and even companies, in various parts of the civilized world at the present time, entirely devoted to the pursuit of this class of work, and it is a source of great satisfaction to know that some of the accomplishments along these lines are truly remarkable and have proved to be of the very greatest utility. Entire works devoted to the life-histories of mammals have now been published with the illustrations obtained in this way, while others have been secured by photographing the species described in their native haunts.

Photography also comes into play when we undertake to study the anatomy and structure of mammals in the prosectorial department of a scientifically organized zoölogical garden, and this is one of the objects to be obtained by such an institution of an importance quite coequal with the one it has in view of instructing the visiting public in the science of animals.

As a matter of fact, any extensive zoölogical garden at all worthy of the name should have upon its grounds one large and commodious building, at least, to be given over to those members of the staff of the institution who are devoted to all the various fields of animal research that have been outlined in several of the foregoing paragraphs of the present article. In such a building as I have in mind, there should be one large room set aside for the use of the staff photographer and his assistants. It should be constructed and equipped in such a manner that animals of any size could be properly photographed in it, and that with the view of having the natural surroundings appear in the pictures thus obtained. Provision should also be made for photography in various other directions, as of the bodies of the animals that have died, and cadavers during different stages of dissection as suggested by the staff prosector. Of course birds, fish, eggs, reptiles, and all else of the kind will come in here, but reference is now being made only to mammals.

Still other rooms in this building should be set aside for the prosectorial department consisting of a thoroughly equipped biological laboratory in every particular. With this in good running order, no material should be allowed to go to waste whatever.

No matter how common the animal that chances to die in the gardens, some good use should be made of it, and the skeleton at least always roughed out, saved, and donated to the osteological collections of some museum or other. In the case of rarer animals, they should be injected, carefully dissected by competent morphologists, and the results, with plates and illustrations prepared by the photographer and artists, published by the institution in its reports and proceedings. Special skeletal and other preparations should be properly preserved and constitute a series for the use and comparison of the anatomist and his staff in his work, and a room or rooms should be devoted to the convenient storage of this class of material. There should also be a section where casts of the grosser parts of dissecting could be made and colored. A few of these could be retained in the collection; but, as they accumulated, a number should be disposed of to educational institutions of various kinds in the country and to medical colleges, and the proceeds applied to defraying some of the expenses of the department now under consideration. The same plan could be adopted in the case of photographs of living animals, and it is really surprising what a revenue they would bring at the present time, so universal is the demand on the part of illustrators for such pictures. Finally, a good working scientific library should be found in this building, especially fitted out for convenient reference on all subjects pertaining to the life-histories of animals of all classes, their structure, geographical distribution, and general biology. When in complete operation, this part of a zoological garden could, if judiciously managed, be made self-sustaining in a great degree, and the amount of information it would be capable of furnishing to biological science would, on account of its amount and value, be quite difficult to estimate. This department of the Regent's Park, under the management of the Zoological Society of London, in London, has, in times past, accomplished wonders along the lines here indicated, and is now doing even more. In fact, when we come to consider the publications they have put forth; the men who have studied there or drawn their inspirations from its very existence, examples and aid, and the enormous amount of material it has furnished in a variety of ways, it is safe to say that it constitutes one of the strongest bulwarks and promulgators of the biological sciences in the entire civilized world. We possess nothing like it yet in this country; but the time is fast approaching when we will, and undoubtedly must, if we have any ambition to keep abreast with other nations in this, one of the real test indices of a nation's true greatness.

Apart from what the study of mammals affords us, both in nature and in confinement, as simply enhancing human knowledge and progress, they may be viewed from still another standpoint, and this is their economic value as a whole. As first conceived, it was my intention to present here some extended statistics on this subject that would prove to be of more or less interest to naturalists, sportsmen, game wardens, legislators, furriers, and dealers in game for the large markets; but upon considering the matter more fully, the idea was, to a greater or less extent, abandoned.

In so far as the mammalia are concerned, there

was a time far back in the earliest periods of the career of the human race, at the very dawn of its history, when the economic value of mammals possessed simply an enormous importance. Men, in those pristine days, when they dressed at all, used the roughly tanned pelts of mammals as their sole raiment. It was long before the era when the prototypes of the race thought of rearing animals in domesticity as a source of food-supply, and they depended wholly upon the chase to furnish their demands for sustenance. Their weapons and crude tools were very often fashioned out of the bones of mammals, and upon the bones of mammals they rudely drew such meager records as they were wont to make of their history. From the claws and teeth of mammals they manufactured their ornaments, and from other parts they made their bow-strings, when such weapons came into use. Indeed, it was an age when men relied almost wholly upon what they secured in the chase to provide themselves with the few and simple things they required to meet the common necessities of life, and fulfil the ends of their barbarous existence. As the centuries rolled by, the dependence on the chase became less and less evident, although the number of animals slain, and the number of pelts used for all purposes, came to be vastly increased. This was due to a variety of causes, as the increase of population and the increase of skill in capturing the animals hunted. But game was abundant and was taken without thought and without stint. No one ever dreamed of such a thing as the extinction of any species of mammal.

Thus things went on for many, many generations, and thus things went on in the early history of this country. When the white man first settled here, who among them ever for a moment gave the extermination of big game a single thought? It was considered unlimited and inexhaustible. So also thought the thousands of Indians distributed in great tribes all over the country from ocean to ocean. In the early provincial towns the markets teemed with big game in plenty, and there seemed to be no end of squirrels and rabbits. The consumption of game was general, and the furs and pelts of animals used in abundance everywhere. Great areas of the country supported no end of game which, from one year's end to the other, was never disturbed or hunted. Fur companies, such as the Hudson's Bay Company and others, were the great moneyed corporations. Almost countless thousands of skins of all the various fur-bearing animals were exported, and they ran into the millions in time.

Furs were comparatively very cheap, and robes, rugs, coats, headgear, and other articles of apparel were made of them for every one, save those in the most moderate circumstances. No one thought anything of a buffalo robe, and the pelt of nearly every other mammal was held in the same estimation. Millions of fur seals were upon the rookeries; sea otters were abundant, and beaver and mink as common as rats and mice.

There came a time, no one can fix the exact date, when all this came to its maximum stage of abundance; a time when the statistics showed the very greatest number of furs and pelts imported or exported; a season when the game markets and personal captures exceeded the bags of any other single

day in history. It may have been along somewhere in the seventeen hundreds,—no one exactly knowing when; but such a day came, and since that day a decline set in and set in steadily toward what was, at first, but a gradual decrease.

Within the last quarter of a century in the United States, this decrease has been extremely rapid. Less and less game was furnished the markets, and, as a matter of fact, the fur trade, as a big industry, no longer existed and many people went entirely out of it. Buffalo robes and sea otter skins came to be almost things of the past and fetched truly fabulous prices in the market, leading to the extermination of the animals. And so it is going on; the rarer American furs are only the luxury for the rich and the very wealthy; it is they, too, who eat of venison and other wild game. The laws are fast tending toward forbidding game to be sold any longer in the market-places, and the time will come when even the eating of wild squirrels and rabbits will be a matter worthy of gossip and a fact to be talked about. The few buffalo robes left will be in the museums, and the existing game on the close-kept preserves of the millionaires.

A CONCEPT OF X-RAY PATHOLOGY.

XIII. ENTEROPATHY.

BY A. J. PACINI, M.D.,

WASHINGTON, D. C.

CHIEF OF LABORATORY AND X-RAY SECTION, HOSPITAL DIVISION,
U. S. PUBLIC HEALTH SERVICE.

DISEASES of the intestine may be classified as follows (Barker):

I. *Inflammations of the intestine, or, inflammatory enteropathies*, including acute and chronic intestinal catarrh, ulcers, appendicitis, colitis and pericolicitis, diverticulitis, proctitis, and certain specific inflammations of the intestine (typhoid fever, dysentery, tuberculosis, cholera, etc.).

II. *Circulatory disturbances, or the circulatory enteropathies*, including intestinal hemorrhage, hemorroids, infarction of the intestine from embolism or thrombosis of the mesenteric vessels.

III. *Enteropathies due to alterations of the lumen, or of the position, of the intestine*, including the stenoses (ileus), dilatations (diffuse and circumscribed), invaginations, axis rotations (volvulus), hernias (external and internal), and enteroptosis.

IV. *Intestinal parasitism, or the parasitic enteropathies*, including teniasis, ascariasis, etc.

V. *Intestinal tumors, or the neoplastic enteropathies*, including intestinal polyposis, cancer, etc.

VI. *Developmental errors, or the congenital enteropathies*, including atresia ani, atresia recti; Hirschsprung's disease (megacolon congenitum); malpositions of the intestines; and Meckel's diverticulum.

VII. *The nervous enteropathies*, including nervous diarrhea, etc.

They are studied for morphology and motility. To elicit the motility it is perhaps best that the patient be allowed regular diet and that neither purge nor enema be administered. A barium meal is fed as for the examination of the stomach and the examination with the x-ray made six hours after the meal and again at twelve, eighteen, twenty-four, thirty-six, and forty-eight hours. The posture is both vertical and horizontal. The exposure is dorsoventral; ventrodorsal for the cecum, sigmoid, and rectum; left lateral for the study of cecal mobility. The intestine is studied as to size, shape, position, and peristalsis.

When the morphology of the intestine is being elicited the colonic tract is first cleansed by the use of an enema and the following barium clysma administered:

Barium sulphate, 4 ounces;
Mucilage of acacia, 2 ounces;
Warm water, 3 pints.

As the clysma is introduced, the colon is studied fluoroscopically and examined especially for spasms, tumors, and kinks due to bands and adhesions.

Inflammatory Enteropathies.—The intestine may become involved in inflammation either in local stretches or in its entirety; or the inflammation may affect only the small or the large bowel. According to the site of inflammatory reaction the condition may be described as a duodenitis, jejunitis, ileitis, colitis, sigmoiditis, or proctitis.

The inflammatory etiology may be primary as the result of (1) dietetic errors; (2) ingestion of indigestible or tainted foods, or very cold beverages; (3) chemical irritants; (4) mechanical irritants. There may be a secondary form of enteropathy due to (1) infections of various sorts; or (2), extensions from adjacent inflammations. On x-ray examination inflamed portions of the colon may be revealed by marked spasticity following a barium clysma which show as a narrowing of the smooth edged shadow of the affected bowel portion; but the x-ray is much more helpful in the diagnosis of chronic inflammation of the intestine than acute.

Chronic enteritis may also manifest as a spastic area in the part of the bowel involved. In mucous colitis, after the barium clysma has been expelled, the mucous shreds that remain infiltrated with the barium suspension may be revealed as ribbon-like strings. There are specific forms of indirect inflammation including tuberculosis, syphilis, actinomycosis, amebic dysentery, and bacillary dysentery. Often the patient is referred for x-ray investigation of the colonic tract by reason of the existence of an unexplained pain in the terminal colon and rectum which radiates down into the thighs. In the absence of x-ray findings the possibility of sacroiliac subluxation, or a neurosis, or uterine or adnexal diseases, or prostatitis, should be considered.

Ulceration of the intestine has been divided (Nothnagel) into the following groups:

Group I.—*Ulcers due to necrosis*: (1) Simple duodenal ulcer; (2) Peptic ulcer of the jejunum; (3) Ulcer following burns of the skin; (4) Embolic and thrombotic ulcer (including the ulcer in polyneuritis); and (5) Amyloid ulcer.

Group II.—*Ulcers due to inflammation*: (1) Catarrhal ulcer; (2) Follicular ulcer; (3) Stercoral or decubital ulcer.

Group III.—*Ulcer due to specific acute infections*: (1) Typhoid ulcer; (2) Dysenteric ulcer; (3) Septic ulcer, etc.

Group IV.—*Ulcer due to specific chronic infections*: (1) Tuberculous ulcer (2) Luetic ulcer, etc.

Group V.—*Ulcer in constitutional diseases*: (1) Scorbatic ulcer; (2) Leukemic ulcer, etc.

Group IV.—*Ulcer in intoxications*: (1) Uremic ulcer; (2) Mercurial ulcer.

Of these, chronic ulcerative colitis requires mention. It consists of a chronic inflammatory condition of the colon of obscure etiology in which the colon shows redness, thickening and infiltration of the mucosa, resulting later in granulation tissue,

polyps, pedunculated papillomas and chronic ulceration and perforation. The x-ray pathology centers on demonstrating the extent of involvement and points of constriction. The most noted x-ray findings are (1) rapid filling of the colon upon introduction of clysmas; (2) narrow and ribbon-like morphology of the large bowel; and (3), absence of haustral markings. Usually in all forms of chronic colitis there is an incompetency of the ileocecal valve; but it is not diagnostically important for it may occur in a large percentage of normal cases. It is often possible actually to demonstrate the papillomatous projections into the lumen of the intestine, especially if these are loose textured and remain saturated or coated with opaque suspension after the clysmas has escaped.

Diverticulitis of the colon is not of too rare occurrence in x-ray experience. The diverticulous sacs become filled with opaque substance and may be visualized as bud-like projections extending outward from the smooth periphery of the bowel; but their most characteristic x-ray pathology rests with the persistence of opaque areas due to prolonged retention of opaque salt four or five days after the meal has passed through. In a case examined recently at a camp about two hundred diverticulous sacs remained filled with opaque retention sixty-four days following a barium feeding.

Chronic Duodenal Ulcer.—Duodenal ulcer occurs most commonly between the ages of twenty-five and forty-five and affects men more frequently than women. Many cases of duodenal ulcer have been diagnosed erroneously as gastric ulcer. Chronic ulcers may either be indurated or non-indurated. The edge is oftentimes terraced with a variable depth to the crater. More usually the ulcer presents a circular punched-out appearance which may become oval or oblong on long standing. The peritoneum over the ulcer assumes a whitish hue and presents the appearance of a radiating scar. It may sometimes become adherent to the intestine. The most common site for the ulcer is the anterior wall about one centimeter distal from the pylorus. There may be a cicatrization which leads to duodenal stenosis followed by secondary dilatation of the stomach. It is rarer for duodenal ulcer to undergo malignant change than for gastric ulcer. The x-ray signs of duodenal ulcer may be direct or indirect. A direct sign includes the demonstration of deformity of the duodenal contour (L. G. Cole). The important x-ray criterion is that the deformity be real and not an artefact. To elicit the deformity the barium-water sediment test, the opaque suspension, morphology test, and motility studies of the stomach and duodenum should be repeated often enough to convince beyond doubt that the duodenal irregularity persists. The deformity may sometimes be characteristic and has been described by Carman as presenting various types as follows:

(1) The *pine-tree* or *branched-coral* type of distortion, (2) the *niche* type, varying in size from that of a wheat-grain to that of a pea, (3) the *incisura* type, single or bilateral, and (4) the *contracted-bulb* type. In addition, he values (1) *duodenal diverticula*, (2) *gastric hypertonus, hyperperistalsis and hypermotility*, (3) *six-hour gastric residue*, (4) *antral dilatation*, and (5) *gastrospasm*, as signs of ulcer of the duodenum when critically interpreted.

If the presence of a deformity is conclusively

demonstrated and its persistence established after the most careful palpation under the fluorescent screen and on repeated plate study, in practically every case constant bulbar deformity is the x-ray sign pathognomonic of duodenal ulcer.

The indirect signs include (1) altered tonus of the stomach; (2) altered gastric peristalsis; (3) altered gastric motility; (4) gastrospasm; and, (5) tenderness over the duodenal deformity elicited on pressure under fluoroscopic examination.

In stomachs of types other than hypertonic the most common change in the presence of duodenal ulcer is that to hypertonicity. It is one of the triad of "hypers" already referred to as strongly indicative of duodenal ulcer.

Hyperperistalsis may vary from a moderate increase of wave depth and frequency to an exaggerated energy of contraction amounting often to gastrospasm.

The hypermotility observed in the shortened emptying time of the stomach has been emphasized especially by Baetjer and Friedenwald, as contributive to the diagnosis of duodenal ulcer.

Appendicitis.—X-ray pathology of the appendix may be revealed as primary or secondary; primary, when actual defects in structure may be visualized from the general morphology of the appendix; and, secondary, when the diseased appendix induces, by reflex, perversions and spastic manifestations in other parts of the gastrointestinal tract with which the appendix is in nervous association.

The appendix fills when there is barium in its vicinity; and as the opaque mass moves along the colonic tract the appendix again empties. If it is desired particularly to study the appendix it would seem best that the patient be examined in the upright position and that a barium feeding be used instead of the opaque clysmas. When the mass reaches the cecum, by the use of the Holzknicht spoon, or the Case modification of the Holzknicht spoon, the opaque material is palpated and pressed with the view to inducing its entrance into the appendix. If, after repeated palpation, the appendix remains unrevealed it argues for obliterative lesion, which, if accompanied by clinical symptoms would point to obliterative appendicitis (described by Morris as harmful involution in the appendix).

There was a time in the early studies of the x-ray findings of the appendix when to visualize a barium filled appendix was interpreted as a sign of pathology; but it now seems certain that pathology is more likely indicated when the appendix fails to fill after diligent palpatory application.

When the lumen of the appendix is patent the opaque mixture enters and may faithfully reveal the length and diameter of the appendiceal canal. In stereoscopic vision the exact location of the appendix may be determined and its anatomical position described to the surgeon as retrocecal, procecal, or however else it may appear. Anywhere in the lumen there may be lodged an obstructive mass which can prevent the entire lumen from becoming completely filled; so that one cannot feel certain that the barium shadow actually represents the entire length of the appendix. After noting the size and the length of the lumen attention is directed to the presence or absence of constrictions or kinks. Constrictions are readily revealed as

marked narrowings anywhere in the course of the appendical canal, which narrowings must persist under vigorous palpation. A kink is inferred when the appendix presents an angulation that refuses to straighten out under diligent manipulation. Adhesions are presumed when the appendix is seen to remain in abnormal and constant relation to any part of the intestine also outlined by the barium meal.

An important x-ray sign rests with the determination of the emptying time or drainage of the appendix. When the barium persists in the appendical lumen after the main barium mass has passed beyond the cecal region, it points to a deficiency in drainage. There are cases recorded (Pirie, quoted by Case) in which the appendical shadow was observed to persist for forty-three days. Another point of importance in connection with the elicitation of appendical pathology rests with the determination under the fluorescent screen of a tender spot located in the region of the appendix.

At most, the direct x-ray signs of appendical disturbances must be reduced to revealing anatomical variations; so that there may be reported the patency of the appendical lumen, its size and length, its straightness or angulation, the presence or absence of constrictions, its free course, or adhesions that bind it to adjoining bowel structures, its emptying time and whether it stands in anatomical relation to a tender point clinically palpated.

The indirect x-ray pathology that results from appendical abnormality is referred usually to the stomach and duodenum. It is in many instances accompanied by contemporaneous changes affecting the gall-bladder. The most frequent manifestation is an impaired gastric motility which affects the emptying time of the stomach so that a small residue, amounting usually to less than twenty-five per cent of the total opaque meal area, persists in the gastric region six hours after administration of the barium meal. In the absence of other x-ray signs of pathology in the stomach or duodenum, six-hour retention with moderate amount should suggest a suspicion of appendical disorder reflected to the stomach (ileopyloric reflex of Barclay). Other signs of pathology centered about the appendix may be those of ideal adhesions or stasis. In this connection the topic of ileocecal incompetency seems to have attracted much discussion.

Insufficiency of Bauhin's valve, permitting a regurgitation of cecal contents into the terminal ileum, may be demonstrated in about twenty per cent of all patients who are examined with the barium clysm. Case considered ileocecal incompetency to be a significant abnormality contributory to ileal stasis. It would seem probable that the question of ileocecal incompetency resolves itself as does the question of water trap stomach. That is, if an ileocecal valve permits regurgitation of the barium clysm into the terminal ileum, the x-ray sign *per se* does not mean anything more than an anatomical register of the fact; and to diagnose ileocecal incompetency as responsible for certain clinical syndromata, not only must the x-ray reveal the incompetency, but the clinician must show by exclusion that the incompetency is the source of disorder.

Changes in Lumen or Position.—A most import-

ant change in intestinal lumen is that incident to acute intestinal obstruction. Acute intestinal obstruction implies a certain stoppage of the passage of intestinal contents. It may be due to mechanical occlusion or due to a paralysis in the motive power of the gut.

Mechanical ileus may be a simple occlusion or may be due to strangulation. Simple occlusion implies an obstruction to the lumen without essential injury to the intestinal wall. It may be due to obduration, tumors, compression from without or spasticity. Under fluoroscopic examination the portion of the intestine proximal to the occlusion becomes gas-distended and is revealed without additional preparation of the patient. In all cases of intestinal obstruction a fluoroscopic survey is much to be recommended as it may oftentimes reveal the exact site of luminal obturation. When the obstruction is due to spastic ileus, which may occur spontaneously or following an abdominal surgical expulsion, the spasm yields to belladonna administered in full therapeutic doses.

Intestinal obstruction may also be the result of strangulation owing to the incarceration of an external hernia. In this condition the possibility of umbilical, obturator, lumbar, and gluteal herniae must be considered in addition to the more frequent inguinal and femoral herniae. The intestine may become incarcerated by reason of an internal hernia (in the duodenjejunal fossa of Treitz, in the foramen epiploicum of Winslow, in the ileoappendicular recess, in the retrocecal recess, or, in the case of a diaphragmatic hernia, in the thorax). In these cases the x-ray examination is decisive, the diagnosis being often arrived at by simple fluoroscopic examination without previous preparation of the patient. Strangulation may result from adhesions after previous operations for appendicitis, cholecystitis, or gynecologic operative inference. It may result as a rotation of the intestinal axis in elderly persons, producing the condition known as valvulus; or in younger patients, particularly in infancy and early childhood, the bowel may invaginate to produce intussusception.

Dynamic or paralytic ileus may be inflammatory, toxic, or reflex.

In general, x-ray study should be undertaken if acute intestinal obstruction is suspected; but a contrast meal should not be fed, neither should a barium clysm be administered until after a fluoroscopic survey has first been made without preparation, and assurance surmised that the meal or clysm is not contraindicated.

The x-ray will differentiate between obstruction of the small intestine and that of the large intestine. The differentiation is effected by a study of the meteoric locus.

Chronic Intestinal Obstructions.—The diagnosis of Chronic intestinal obstruction is elicited by the x-ray through the joint observation of intestinal dilatation accompanied by hypertrophy of the bowel wall. In chronic obstruction the stenosis may be due either to (1) a concentric narrowing; or, (2) a pressure from outside the bowel. Concentric narrowing may be due to carcinoma, tuberculosis, lues, or the scar of a non-specific ulcer. Tuberculosis occurs at any age and affects more particularly the small intestine or the cecum. Enteric tuberculosis

usually assumes one of three types; nodular, ulcerative or fibrous. In the nodular type the lesion consists of conglomerative tubercles, generally extraluminal. This type barely permits of identification by the x-ray. With it there is usually associated the ulcerative type which is revealed on the plate by an irregularity of the bowel contour, which irregularity increases to the point where, in the terminal stages, it produces obstructions. The fibrous type induces a proliferation of connective tissue which stiffens the bowel wall and leads to an irregularity in the contour and, therefore, affords practically an identical picture to the ulcerative type.

The major x-ray signs of tuberculous colitis are; filling-defects, spastic phenomena and obstruction (Carman). To these hypermotility has been added (Brown and Sampson). Hypermotility is apparently due to the accompanying achylia or to diarrhea and is not in itself diagnostic of tuberculous colitis, though its association with the condition is frequent and deserving of emphasis. Spasm manifests in practically all gastric intestinal lesions and is, therefore, only of contributory value in the diagnosis from the x-ray plate.

Carcinoma generally affects the large intestine, after the age of thirty years, and seems to favor the rectum, sigmoid, cecum or right or left flexure of the colon. Luetic stricture, when it occurs, most usually involves the rectum.

Chronic stenosis may be due to pressure from without as direct compression from a retroflexed gravid uterus, carcinoma of the uterus or ovary, or kidney, or sarcoma. It may be due to a fixation of the bowel by adhesions or bands due to inflammation or to an infiltration of the intestinal wall such as pericolicitis, Jackson's membrane, Iscovesco's membrane, Treve's band and allied conditions. The x-ray study is of the greatest help in the differential diagnosis of these conditions.

Dilatations of the Intestine.—Dilatations of the intestine may be diffuse or circumscribed. The diffuse form may occur as a proximal dilatation to intestinal obstruction of whatever sort, or it may be a congenital malformation. Circumscribed dilatations may be found in any part of the large intestine. When acquired they are usually diverticular and are most common in the sigmoid and descending colons.

Dilatation of the ileum reveals as a diffuse widening of the lumen of the lower part of the ileum. It is accompanied by an undue delay in the passage of intestinal contents through it. It may arise as the result of organic obstruction in the ileocecal region due to tuberculosis, cancer and actinomycotic lesions; but aside from these there appear to be three principal causes for ileal dilatation and ileal stasis. According to Barker these are:

1. Adhesions in the region of the terminal ileum causing compression or kinking of the bowel and thus obstructing its lumen; these adhesions may be the result of the regular embryological peritonitis that occurs in all mammalian embryos (A. Keith), or of a peritonitis occurring after birth; in the bibliography, much has been made of Lane's kink, as a cause of ileal stasis.

2. Spasm of the terminal four inches of the ileum, known as the ileocecal sphincter mechanism

(Keith, Hertz, Case); normally, this sphincter is responsible for a certain delay of the chyme in the lower ileum; in certain pathological states, especially in acute and chronic appendicitis, this ileal delay is pathologically lengthened owing to spasm of the sphincter; dilatation of the ileum proximal to the sphincter and ileal stasis result.

3. Incompetency of the valvula coli (or ileocecal valve); according to J. T. Case, this reflux of colonic contents into the ileum is the commonest cause of diffuse dilatation of the ileum, and of ileal stasis. Normally, the valvula coli is competent, but in about one out of every six patients presenting gastrointestinal symptoms examined by x-ray methods, the valvula coli has been found incompetent (Case). Incompetency may be due to congenital defect in the valve, or, more often to colonic stasis due to bands, adhesions, etc.; most patients with incompetency are constipated.

Intestinal Stasis.—It would appear that intestinal stasis may be considered as a chronic disease due to the retention for too long a time of the intestinal contents. In many instances there are certain bands to which Lane has directed much attention and attributes the etiologic ancestry of these bands as the result of the effects of upright posture. As the upright posture is assumed the dropping of the viscera exert a drag upon the mesentery which results in the formation of thickened bands (compensatory perhaps). These bands become so thick and strong in certain parts as to form supplementary mesenteries tending to support the bowel. If these adhesions (says Jordan) were equally strong in all parts, the force incident to supporting the structures in their new posture would be equally distributed. But the bands may be strong in some places and weak or absent in others; and consequently the bowel may be supported at certain points where the bands are strong and kinked with varying degrees of mechanical obstruction at those places where the bands are weak or absent. It would seem that there are certain points at which these kinks are especially liable to occur. Following along the digestive canal from the stomach the first point is said to be at the third part of the duodenum near the commencement of the jejunum. Jordan goes on to describe other points in the tract including the lower end of the ileum, the appendix, the hepatic flexure, the splenic flexure, the sigmoid loop, and the rectum. With accurate time study of intestinal motility a relative delay or stasis of food in any part of the intestine may be determined by the x-ray; and if the delay occurs at a region where evident abnormal morphology can be shown, an x-ray diagnosis of anatomical intestinal stasis is permissible. It remains for the clinician to decide whether the stasis is responsible for the clinical condition revealed by the patient.

(To be continued.)

The Klippel-Feil Syndrome.—Lance showed a child of 12 years treated during several years for suboccipital Pott's. He found the syndrome described by Klippel and Feil, to wit: Short neck, low implantation of hair, limitation of movements of head. The author also showed a radiograph of a child of 6 years with spina bifida of the entire cervical spine and uppermost dorsal vertebrae, in which an unsuccessful operation had been performed for torticollis.—*Le Bulletin Médical.*

TETANUS, WITH RECOVERY, SHOWING SOME UNUSUAL FEATURES.

BY B. L. SULZBEACHER, M.D.,

KANSAS CITY, MO.

A CASE of tetanus with recovery, which presented some interesting phenomena, was recently under observation. Tetanus developed on the fifteenth day following an injury even though a prophylactic dose of antitetanic serum was given at the time the injury was received, and in which the wound was open in its entirety after the tenth day.

The case in question emphasizes the necessity of a large dose of antitoxin, as an absolute prophylactic, and the advisability of immediate cultures, aerobic and anaerobic.

A child, M. B., *et.* 21 months, was run over by a motor truck. On admission to the hospital and under ether anesthesia, the injury was found as follows: The skin of the right leg presented a very jagged, torn appearance, running from a point three inches above the knee on the inner aspect of the thigh around the leg,

the temperature rose to 104.8°, and the flaps had become somewhat gangrenous looking. Carrel tubes were inserted after removal of several stitches and intermittent irrigation with Dakin's solution was instituted. The temperature immediately fell approximately three degrees and in five days had decreased 4.4°. The flaps were hopeless on the tenth day. They were completely removed and disclosed underneath quantities of evil smelling pus and detritus, which previous culture had shown to be *Streptococcus hemolyticus* and *Staphylococcus albus*. Anaerobic cultures were not made at this time.

At this point it is rather remarkable to note that the muscles were found to be united in spite of the nature and seeming virulence of the infection. The patient's general condition improved daily, likewise the local condition, the wound showed healthy granulation tissue throughout.

On the afternoon of the fifteenth day it was noticed that the child's pupils were widely dilated and accommodation relaxed, giving the eyes a peculiar staring appearance. Later in the evening close observation revealed beginning rigidity of the extensor muscle of the neck and the masseter muscles. Slight tonic convulsions of the upper extremities accompanied by stertorous breathing occurred at intervals of twenty to thirty minutes. The arms were flexed and rigid. Lum-

through the popliteal space to a point three inches below the head of the fibula, thence across the front, and ended on the inner side of the leg at the junction of its middle and lower thirds. The lower flap was everted much as a stocking would be pulled over the leg and carried on its inner surface portions of the tibialis anticus anteriorly, and the gastrocnemius and soleus muscles posteriorly. The popliteal artery was clearly visualized to the point of its bifurcation, likewise the deep veins.

Both the upper and lower flaps in places were torn loose from the fascia. The tibia was fractured in a diagonal line in its upper third, but the fragments were in good position. The joint capsule was opened posteriorly for a distance of about two centimeters. Hemorrhage was very free, coming from the superficial veins. The wound was thoroughly cleansed with physiological saline solution and later drenched with McDonald's solution. Repair of the torn muscles was attempted, drainage tubes being inserted in the depths of the wound and the skin closed with interrupted silkworm gut sutures, care being taken to allow space for drainage between each stitch. The little patient, though badly shocked, was placed in bed, stimulated, and immediately given 500 units of tetanus antitoxin.

Progress was not unusual until the fourth day, when

bar puncture was done, and the negative findings excluded possible meningeal irritation from the dehydration of hyperpyrexia or infective diarrhea. On these findings and symptoms the diagnosis of tetanus was established.

Owing to the fact that a prophylactic dose of antitoxin had been given fear was held lest anaphylaxis might develop on its subsequent use. The patient was thoroughly tested with a small dose given subcutaneously and observed for one hour. No reaction having developed, a full dose of 5,000 units every eight hours. Chloral hydrate, grs. ii, was given at hourly intervals to control convulsions. The injections for the greater part were given subcutaneously and in the deep tissues of the wound. In all 14,000 units were used.

Convulsions ceased within twelve hours and rigidity entirely disappeared in thirty-six hours. A portion of the bedside chart, with report of medication and temperature, is herewith given.

Later attempt to gain confirmation of tetanus by anaerobic cultures proved negative, which, however, in the light of the development of the case, its history and conduct, would only be of academic interest.

Considerable difficulty was encountered in feeding

the child, and tube feedings were resorted to on various occasions.

Further progress has been uneventful, and at the present writing the second skin grafting operation has been completed successfully.

The valuable experience gained may be summarized: (a) as to the need of large prophylactic doses of serum; (b) the early recognition of symptoms; (c) the persistent and regular serum therapy; (d) importance of anaerobic cultures in all accident cases. This case illustrated rather unusual features in the retarded development of its symptoms and in their short duration; these lasting only thirty-six hours.

I am indebted to Drs. L. S. Milne, D. Walthall and S. McCutcheon for assistance in the above case.

412 ARGYLE BUILDING.

REPORT OF TWO CASES OF ACHOLURIC JAUNDICE, FAMILIAL TYPE, WITH SPLENOMEGALY.

By DAVID H. HALLOCK, A.M., M.D.,

SOUTHAMPTON, N. Y.

CASES for diagnosis presenting chronic enlargement of the spleen are interesting because of their relative rarity, and also occasionally because of difficulty in arriving at a definite diagnosis in a given case. After a tentative diagnosis has been reached, lack of agreement in nomenclature renders the conveyance of our conception of the case to others by a single term difficult. Consequently we try to name the disease and hasten immediately to qualify the diagnosis with as many of the prominent symptoms or physical signs as are present. Hence the heading of this article.

The following more common causes of splenomegaly may be mentioned: Infants: Syphilis, rachitis, tuberculosis, anemia (especially von Jaksch's), acute infections (especially malaria). Adults: Above, as well as amyloid, leucemia, Banti's (splenic anemia), Gaucher's, and Hodgkin's, anemias (especially pernicious), acholuric jaundice, acquired or familial.

It is the purpose of this article to report two cases of the last named, first recognized by Minowski as an entity.

CASE I.—A. F., male, 16, single, clerk, admitted July 22, 1920, Hosp. No. 3848. Mother is living and well. Father died of "liver trouble"; was of a yellowish tinge of skin for many years. Paternal grandfather also died of "liver trouble"; was yellow like patient for a long time. Had measles and diphtheria without complications. Enlarged tonsils and adenoids removed. Denies lues by sign and symptom.

The present illness began at three years of age with a symptomless jaundice. The entire skin took on a faint yellow tinge which fluctuated in intensity from time to time. At five years lassitude first appeared with dyspnea on slight exertion. At no time except during the two intercurrent infections mentioned above was the patient acutely ill; nor has the patient ever felt in as good health as others appear to be. During school he failed in two classes, having neither the desire nor the energy to study. He left school as early as the law permitted and engaged in business, but with the same lack of interest and want of energy.

Symptoms.—The sclerae are jaundiced continually with varying intensity. There is occasional epistaxis, some dyspnea on exertion, no cough nor expectoration nor loss of weight; occasional attacks of palpitation

*From the Medical Service, Southampton Hospital.

of the heart. There are no gastrointestinal symptoms except constipation; some pain in right upper quadrant on exertion is complained of. No genito-urinary symptoms, except that the urine is usually very dark. The skin has been yellow in color constantly, varying in intensity. No night-sweats, itching, or furunculosis.

Physical Examination.—Fairly well nourished and developed boy, rather pale. Skin and sclerae have a faint yellowish tinge as of jaundice. The pupils react to light and in accommodation. The cervical nodes on right side are enlarged, but there is no general enlargement of lymph nodes. Examination of the lungs is negative. The apex beat is one cm. outside the nipple line; it is forceful and sounds of good quality. The abdomen is soft. Kidneys and liver not felt. The spleen is definitely felt descending 15 cm. below the costal margin in the nipple line. No notch is felt. Stomach tympany is displaced to the right and upward. The mass descends with inspiration. Examination of the extremities is negative. The reflexes are all slightly exaggerated. The skin is of a slight yellowish tinge throughout and pale; acne pustules are on face.

Special Examinations.—The x-ray of the liver is negative for stone or enlargement. Urinalysis is negative except for a considerable amount of indican and a few white blood cells. Bile and urobilin absent. Blood examination, Hgb., 74 per cent.; R. B. C., 4,800,000; W. B. C., 6,900; polymorphonuclears, 60 per cent., lymphocytes, 30 per cent., large mononuclears, 2 per cent.; transitionals, 2 per cent.

Stool examination shows a very faint trace of occult blood; bilirubin and hydrobilirubin present; no ova nor parasites. The Wassermann is negative (two laboratories). The Wassermann of the mother is also negative (two laboratories). McLean Index: 61 per cent. Acidosis coefficient, 6.8. Fragility test for R. B. cells: Hemolysis in this case began in 0.52 per cent. sol. NaCl. (In a normal blood it begins in 0.42 per cent. sol. of NaCl.) Hemolysis in this case was complete in 0.444 per cent. sol. NaCl. (In a normal blood it is complete in 0.35 per cent. sol. NaCl.)

From the above findings and investigations a diagnosis of acholuric jaundice of familial type with splenomegaly, was made.

Treatment consisted of an alkaline tonic, sodium cacodylate hypodermically, and thereafter Donovan's solution by mouth. Splenectomy was advised but refused.

When last heard from, January 2, 1921, the patient was deriving much benefit from the climate of California, enjoying the best health yet.

CASE II.—S. S., 61, female, married, first seen February 7, 1915. Her sister died of biliousness, being pale and jaundiced. The patient has had measles, typhoid fever, malaria, mumps, scarlet fever, diphtheria, double pneumonia, tonsillitis, and grippe without complications. She was yellow when a baby, and since then has been occasionally jaundiced without pain but usually with indigestion. The attacks of jaundice last from two to seven days. During the intervals the appetite and digestion are good, and bowels regular.

The present trouble began five years ago with pain in the pit of the stomach followed the next day by jaundice. She has been worse during the past year. The pain radiates to the umbilicus and is accompanied by distention. The last attack occurred twelve days ago and was brought on by hard work. The urine passed during an attack of jaundice is dark.

Physical Examination.—Fairly well nourished and developed woman lying quietly in bed, in no acute pain, skin jaundiced. The pupils react to light and in accommodation. The sclerae have a light yellow tinge. The nose gives evidence of recent epistaxis. The tonsils are enlarged. The apex beat is in the fourth interspace, 14½ cm. from the midsternal line. Relative cardiac dullness in the second interspace extends 16½ cm. to the left and 3½ cm. to the right of the midsternal line. There is a systolic shock with thrill over the precordium and a loud mitral systolic murmur transmitted outward. There is also an aortic systolic murmur. The pulmonary second sound is accentuated. Pulse 70 to 80. Blood pressure, 120/65. The wall of the abdomen is thin with diastasis recti. The liver edge is felt 8 cm. below the costal margin in the mid-

clavicular line. The surface is smooth. At the lower edge there is a small rounded mass (gall-bladder). The left side of the abdomen is full. The spleen is palpable in the pelvis $7\frac{1}{2}$ cm. below the costal margin, firm, freely movable, tender. No notches are felt. Extremities, negative.

Special Examinations.—Red blood cells, 4,000,000; white cells, 8,000; Hgb., 75 per cent. Polymorphonuclears, 60 per cent.; Mononuclears, 35 per cent.; slight anisocytosis of the red cells. Fragility test: Hemolysis began in 0.54 per cent. and was complete in 0.42 per cent. saline solution in three hours with washed corpuscles. Vital Stain: 13 per cent. took the vital stain, 1 per cent. granular and 12 per cent. diffuse. Urinalysis negative except for a considerable trace of albumin and the presence of urobilin and urobilinogen. Wassermann negative with blood serum. Blood serum showed the presence of bile pigments. Bile present in the feces.

Diagnosis: Acholuric jaundice, familial type, with splenomegaly cholelithiasis, and chronic cholecystitis; chronic cardiovascular disease.

The conclusions we may draw from these two cases are that this disease may last over a period of years and be compatible with fair or even good health. In diagnosis the main points are: (1) familial occurrence, (2) splenomegaly, (3) slight persistent jaundice, (4) acholuria and normal stools, (5) increased fragility of the red blood cells, (6) associated anemia, (7) increased vital staining of the red blood cells.

FOREIGN BODIES IN THE ABDOMEN.

REPORT OF A CASE OF EIGHT YEARS' DURATION.*

By HARRY J. HARTZ, M.D.,

PHILADELPHIA, PA.

By the term foreign body in the abdomen it is generally understood that such body has been introduced in the abdominal cavity from without or from adjacent viscera. In the majority of instances these bodies are left in the abdomen accidentally during some operative procedure and are generally sponges or instruments, but may be suture material, rubber tubing, or wicks of gauze.

The symptoms that a foreign body produces in the abdomen depend primarily upon whether such body is septic or aseptic. If septic, it at once produces acute disturbances such as abscess or a generalized peritonitis with the consequent clinical syndromes, frequently terminating the life of the individual. If the body is aseptic, the tendency for it is to become encapsulated and manifest no symptoms for months or years. The isolation may still further be strengthened by adhesions between loops of intestines, the omentum, some organ, or the abdominal parietes.

In recent cases, sponges tend to escape spontaneously through the abdominal wound. If encapsulated they sooner or later cause symptoms by mechanical irritation or pressure on surrounding organs. Secondary infection or necrosis ensues and the foreign body is extruded into the lumen of the bowel or bladder, if adjacent to these hollow viscera.

The symptoms at first are obscure abdominal pains with a tendency to intestinal obstruction. The patient does not recuperate from the operation as rapidly as one would expect. There is generally

a slight recurrent fever which yields to rest and diet and manifests itself again as soon as the patient is up and about. At variable periods the symptoms become intensified and point to an acute intraabdominal disturbance which may demand a secondary operation with disclosure of the cause of trouble.

The symptoms generally subside spontaneously with the escape of the sponge through a broken-down scar or through a necrosed area in the small or large intestine which had become isolated by previous adhesions.

In cases of long standing, when the gauze has become encapsulated, there may be no symptoms, or these may be limited to a localized tumor with slight tenderness.

Neugebauer¹ in 1907 reported a total of 236 foreign bodies found in the abdomen. This probably represents but a small number, since many such cases are not reported.

Findley² reviewed a large number of cases and refers to several interesting occurrences.

Van Marter and Carsen in 1904, in an operation for full term ectopic pregnancy, left a gauze sponge measuring 36 x 18 inches in the abdomen; this was expelled through the rectum seventy-five days after the operation. The patient made a full recovery.

Dillard³ reports a similar case of sponge being passed by the bowel several weeks after the operation for removal of ovarian cyst.

Gruzdew⁴ recorded the case of a woman fifty-eight years, who presented herself in his clinic with a foreign metallic body protruding through the abdominal wall. On vaginal examination the handle of the instrument was felt in the cul-de-sac of Douglas, and was removed per vaginam. Recovery was rapid. The instrument was a clamp twenty cm. in length.

Stewart Ferguson⁵ reported a case in which ten and a half years after an ovariectomy a forceps was found in the left iliac fossa which had caused local pain and bladder disturbances. It had ulcerated into the bowel. The forceps was removed and an intestinal anastomosis performed and recovery followed.

Schachner⁶ in a report of 155 cases in 1901 gives a mortality of 50 per cent. in the cases where foreign bodies were accidentally left in the abdominal cavity. In 70 per cent. the foreign body was a sponge or sponges; in 25 per cent. artery clamps and in the remaining 5 per cent. drainage tubes, finger rings, and miscellaneous articles.

Monro⁷ is not cognizant of any system for preventing this accident that is infallible. As a rule coolness and alertness in trying emergencies, uniform methods in assistance and operative technique, avoidance of the use of small sponges or instruments within the cavity, some form of checking the packs or wicks used in which the surgeon and his corps of assistants are trained, an intelligent sponge count before and after operation, and the elimination of outside distractions, will materially lessen the chances of these unfortunate accidents.

The following is a report of a case from the service of Professor E. E. Montgomery through whose kind permission I have the privilege of reporting this history.

The patient, Mrs. P. T., age 57, was admitted to St. Joseph's Hospital, August 25, 1911. She was a well

*Report presented with specimens, at a meeting of the St. Joseph's Hospital Clinical Conference Society, October 19, 1920.

nourished, somewhat flabby, medium statured woman. Abdomen showed relaxation and umbilical hernia. Her chief complaint was inability to walk well, nervousness, umbilical hernia. She had had the usual diseases of childhood. A fibroid tumor was removed eight years ago in Buffalo, N. Y. She has been a widow for four years, was married for twenty-six years, no pregnancies; puberty at 16, menses regular, menopause at fifty-two years. She had umbilical hernia for eight years, following immediately the operation mentioned. For several months she has complained of weakness and inability to walk.

The operation was performed by Dr. E. E. Montgomery through a ventral abdominal incision. The uterus, one tube and ovary, and a piece of omentum containing a mass were removed. The patient remained in the hospital five weeks and made a good recovery.

Laboratory Report No. 5,613.—The gross specimen is in three parts, one is the uterus with one tube and ovary. The uterus is 10 by 6.5 by 4 cms. On the surface and in the wall are several hard nodules. The anterior surface is smooth and shows several strands of wire suture material. The posterior surface is roughened at the site of the tumor which was removed. The latter, egg shaped, is 8 x 5 x 5 cms. and calcareous throughout. The largest piece of omentum is 22 x 4 x 2 cms. At one end is an enlargement five cm. in diameter, that is moderately firm. Incision shows it to contain a sponge, which was left in the abdomen at a previous operation eight years ago.

The interesting features in this case are: (a) the sponge enclosed in its entirety by the omentum and freely movable in the abdominal cavity; (b) the heavy silver wire used as suture material in the previous operation for ventrofixation of the uterus; (c) the dense calcareous fibroid attached to posterior surface of uterus and firmly adherent to Douglas' cul-de-sac.

Medicolegal Notes.

Alabama Legislature Within Its Power in Making State Medical Association the State Board of Health.—In a suit by taxpayers to enjoin the payment of funds appropriated for use by the Alabama State Board of Health, the complainants contended, not that the State Legislature is without authority to create a State board of health and empower it to administer the public health laws, but that such a board must be a State board, which is an arm of the State government, and whose members must be State officials, chosen as such and amenable to public control and supervision; and that it is beyond the power of the Legislature to confer upon a private corporation composed of private individuals any part of the sovereign power of the State in that behalf. The theory of the bill was that the State Board of Health, as constituted by the statutes of Alabama since 1875, is an illegal body, because it is in fact a private corporation and because the Legislature cannot make such a private corporation a repository of governmental powers, even for purely administrative purposes. By the act of February 19, 1875, it was provided that the Medical Association of the State of Alabama, incorporated by statute in 1850, as organized by its constitution adopted in 1873, should be the board of health of the State of Alabama. This provision has been reenacted in every code of the

State down to the act of September 29, 1919, which recognizes the health laws of the State. The membership of the medical association is, under its constitution, made up of four classes: (1) Members of county medical associations holding a charter from the State association, who cannot vote or hold office; (2) two delegates from each county association; (3) 100 counselors selected from the permanent members of the State association; and (4) correspondents, who are distinguished nonresident physicians or ex-counselors of ten years' service as such. The chief point of attack in the structure of the State Board of Health was in the mode of selecting its members, the objection being that in effect they were selected by the vote of members of medical association of the State, who, with respect to such action, were acting in a private capacity, in accordance with the rules of their association, and without responsibility to the State or to the people. Conceding this as true, and admitting the moral force of the objection, the Alabama Supreme Court is of opinion that no constitutional inhibition is thereby violated. The power of private corporate selection here complained of is indirect and not immediate, for, after all, the Legislature designates the board of health, though it selects therefor a corporate organization whose individual membership is predetermined by the rules of that corporation. But even so there is a legislative adoption of those rules as the appropriate mode of selection, and it is clearly within the power of the Legislature to direct and formulate those rules and to change them at its pleasure. But, those considerations aside, the court cited authorities strongly supporting the authority of the Legislature to vest in private associations of this sort the power to select or appoint the members of State boards constituted for the administration of public affairs. In *Overshiner v. State*, 156 Ind. 187, it was held that the appointment of members of the State Board of Dental Examiners may be vested in the State Dental Association. In *Scholle v. State*, 90 Md. 729, it was held that a private corporation may be legally authorized to appoint a board of medical examiners. In *Exparte Gerino*, 143 Cal. 412, it was held that the Legislature could authorize certain medical societies (not public corporations) to name or appoint the members of the State board of health. These decisions were rendered under the influence of constitutional provisions regulating the organization of the State government not materially different from those of Alabama. Moreover, the court was of opinion, having regard to the organization, aims and activities of the medical association, and its relation to the State Board of Health and to the public welfare in general, that it is a quasi public corporation, charged with duties and responsibilities which it cannot evade, and is therefore, even under a much narrower construction of legislative power than the court accorded, an appropriate agency for service in the administration of the health laws of the State. Judgment sustaining demurrer to the bill was therefore affirmed.—*Parke v. Bradley*, Alabama Supreme Court, 86 So. 28.

Statute Authorizing Removal of Mobile Medical College Not Unconstitutional.—The Alabama Supreme Court holds that section 267 of the State Constitution, prohibiting the removal of the University of Alabama and other institutions there named, except upon a vote of two-thirds of the Legislature, when considered in connection with section 264, applies to the removal of the university, as located at Tuscaloosa when the Constitution was adopted, and not to the Mobile Medical College, a mere subsidiary located in another Congressional district. Under Alabama Acts 1907, p. 357, dissolving the charter of the Medical College and placing the ownership of its property in the board of trustees of the university, the court holds that the Medical College became a State agency, entitling the State to move it from Mobile notwithstanding provisions of the act that it should remain in Mobile for all time. The direction in Acts 1915, p. 133, to the State University trustees to remove the university medical department from Mobile whenever the Council on Medical Education of the American Medical Association informs them that it proposes to lower the classification of such medical department is held to be constitutional and not to be a delegation of legislative power.—*Stevens v. Thames*, Alabama Supreme Court, 86 So. 77.

PYELITIS IN INFANCY AND CHILDHOOD.

ANYONE anxious to see rational conceptions applied to etiology, or more especially to therapy, will find ample room for endeavor in the pyelitis of infancy and childhood. Too many things are being taken for granted. And some of the therapeutic measures sanctioned by the best medical opinion today are being employed with little or no knowledge of how or why they are of value.

That the disease is twice as common in babies under two, that it is about three times as common in girl babies, that the infecting organism is the *Bacillus coli* in the great majority of cases, these are well attested, readily demonstrable facts. How the infection reaches the kidney pelvis, however, is a matter which will bear much clarification. Too many assume that the great predilection of the disease for girl babies must indicate that the infection is ascending—from the vagina, soiled with feces, up the short urethra to the bladder, thence up the ureter to the kidney pelvis. Granting normal ureteral sphincters, the difficulty of sufficient colon bacilli making their way upstream to produce pyelitis, must be apparent. Sedgwick and Huene-kens failed to produce pyelitis in guinea-pigs by injecting colon bacilli through ureteral catheters. Sweet and Stewart tried cutting the ureters and sewing the ends into the intestine. No infection of the kidney-pelves resulted except through the lymphatics.

Colon bacilli have been found in greatest numbers in the region of the ileocecal valve. A direct connection between the lymphatics of the kidneys (particularly the right kidney) and those of the large intestine, has been demonstrated (Franke). There is thus a strong probability that the infection starts by the lymphatic route. The work of Crabtree and Cabot, Richard M. Smith, and others, furnishes strong evidence that the disease may be hematogenous in origin.

It is often by no means easy to make a diagnosis of pyelitis. Symptoms range all the way from none at all to those of extreme severity in "fulminating" cases. The frequency of symptoms simulating those of central nervous disease is receiving more and more recognition. Even microscopic examination of the urine often leaves one in doubt as to

whether or not pyelitis is present. What shall be called pyuria? Six or eight white cells per field in an uncentrifuged specimen? Must there be clumping? No absolute answer can be given. It must often be left to individual judgment and experience, or to the "therapeutic test."

The rational treatment of pyelitis requires an accurate knowledge of the habits of the *Bacillus coli*. Inasmuch as this organism produces acid by the fermentation of sugars, it has commonly been thought that acid is required for its proper growth, and that this accounts for the good results of alkali therapy. The work of Shohl proves that the colon bacillus will grow in media of widely varying hydrogen-ion-concentration. In fact, cultures of *B. coli* tend to make acid media alkaline, and alkaline media acid, until a level of hydrogen-ion-concentration of 8 is reached. Clearly, neither acid therapy with urotropin nor alkali therapy with sodium bicarbonate or citrate can accomplish much against an organism which survives a pH of from 4.7 to 9. Even maximum doses cannot render the urine sufficiently acid or alkaline at the level of the kidney pelvis, especially as there is so little time for "disinfecting" drugs to act at this level. The fact is, most of us force liquids in this disease—a measure known to be of great value, though one which theoretically allows our drugs less time to act.

Alkali therapy is certainly more popular, and deservedly so. As suggested by Marriott, it probably works in two ways: (1) It bathes the inflamed kidney pelvis with non-irritating instead of irritating (acid) liquid. (Compare the effect of high acidity upon gastric ulcer.) (2) It in some way increases tissue-immunity.

Concerning vaccine therapy in this condition, Crabtree and Cabot have found that vaccines help systemic symptoms without curing the disease; a fact which is readily understood when we consider that antibodies in the blood do not necessarily mean antibodies in the urine, owing to the changes which take place in the processes of secretion and excretion.

Recent researches upon pyelitis, of which the above are examples, should remind pediatricians that rational conceptions of etiology and therapy, in this disease as in all others, deserve to prevail, and ultimately accomplish most. Certainly, it does not pay to take too much for granted.

THE SYMPTOMS OF TUBERCULOUS MENINGITIS IN ADULTS.

THE classical symptomatology of tuberculous meningitis met with in children is occasionally realized in adults, but this is rare. It must be admitted that when it does occur it is obscure, while in advanced phthisis it is often overlooked. The majority of cases in adults give rise to purely motor accidents, such as hemiplegia, with or without Jacksonian epilepsy and radial paralysis. In other instances the hemiplegia may be either right or left brachial or crural monoplegia, chorea, athetosis, or finally

a comatose state. Some patients begin with aphasia or verbal deafness, or the process at the outset may assume the clinical aspect of cerebrospinal meningitis. From this enumeration it is evident that the onset of tuberculous meningitis in adults is far from being like that met with in children. Perhaps, as Chantemesse has pointed out, there may be an early premonitory phrase during which an attentive examination might have detected disturbances of the intellect or affectivity, but this is not common, although a few instances have been recorded by Vivant in particular. It is evident that the kind of onset will considerably influence the evolution of the process. A patient suddenly develops coma and dies in a few days without regaining consciousness, but aside from such tragic circumstances there are a number of varieties and forms, intermediary, so to speak, which have a duration of five or six months from the onset to the time of death. For example, a patient may be seized with a right hemiplegia, preceded by an attack of epilepsy, and remain without any change for five months, when coma develops and death occurs some days later. Nothing can be found in the general condition of the patient or the hemiplegia that throws any light on the true cause of the condition.

In most instances the hemiplegia is of the limp variety without increase of the reflexes and with Babinski's sign present, while the frequent association of convulsive and paralytic phenomena is hardly sufficient to enlighten the clinician as to the real nature of the affection. Occasionally cases are met with where the paralytic phenomena of the onset are followed by significant symptoms, such as persistent headache, unequal pupils, vasomotor or sphincteric disturbances, stupor, etc., testifying to a tuberculous implication of the meninges. What is striking is the absence, at least at first, of meningeal phenomena. Hemiplegia, monoplegia, chorea, aphasia, etc., are the various conditions presented by the patients. The situation may improve for a while, but after a certain lapse of time the patient dies in coma, or, on the other hand, the affection becomes confirmed by the appearance of meningeal symptoms. Then the symptomatic picture becomes clear and vasomotor disturbances, typical cerebral vomiting, unequal pupils, Kernig's sign, and finally coma successively complete the clinical picture. The temperature chart has nothing characteristic. At times there is hardly any rise until toward the end of the process; at others there is a temperature oscillating around 102° , with remissions to normal; then the mercury rises to between 102° and 104° , and there remains. Occasionally a curious phenomenon occurs: the temperature, which was high, insensibly drops and death takes place in hypothermia.

No indications can, therefore, be deduced from the temperature, but what is really interesting and implants a special stamp upon these cases of meningitis is their manner of onset, so that in this respect, aside from the classical form rare in adults, a series of forms may be described based principally on the kind of onset offered: The first is the

latent form, which does not declare itself for a long time, then suddenly breaks out in an apoplectiform, epileptiform, or delirious attack, rapidly followed by fatal coma. The *delirious* form in which for months there is no other manifestation than perversions of the intellect or affectivity, or a variable degree of delirium, often ending in acute mania. The *spinal* form, which is most commonly encountered in tuberculous subjects and presents the clinical aspects of ascending myelitis. And finally, the *hemiplegic* form characterized by the localization of a patch of meningitis over the psychomotor zones. Jaccoud describes a *slow and remittent* type in which a phthisical patient is seized with headache, vomiting, and weakness which last for several days and then remit, only to recur five to eight days later. After several similar attacks the meningeal symptoms appear. In Jaccoud's *sudden delirious* form a tuberculous subject is taken with intense headache lasting for twenty-four hours, then coma for one or two days, followed by violent delirium, and after a few hours coma and death supervene. This observer also describes a form the initial phenomenon of which is either an epileptiform or an aphasic attack, and still another that he calls *latent*, with two modalities: one with headache, aggravation of the general condition, but no fever; the second with gastric disturbances and headache, also apyretic. The patient weakens and finally is carried off by some cerebral symptom.

Such are the various clinical types of tuberculous meningitis in adults, the latent forms especially characterizing the process in subjects at this time of life.

THE UNDETERMINED POISONS OF THE DIPHThERIA BACILLUS.

It is at present difficult to say just what part the various poisons of the bacillus of diphtheria play in this disease. In spite of the immense strides made since the discovery of diphtheritic toxin, it appears that this toxin cannot by itself produce all the morbid phenomena developing in diphtheria and that accidents occur whose real pathogenesis escapes us. In this group should be especially included the late accidents, such as diphtheritic paralysis and the fatal syncope of convalescence. Evidently there are factors which still escape us and it is difficult to understand why paralyses occur one or two months after diphtheritic infection when the patient is in full convalescence, since the accidents do not appear to be in any way related to the gravity of the primary localization of the disease.

An attempt has been made to compare experimental diphtheria in the guinea-pig, rabbit, and dog with spontaneous diphtheria in man, and still there is nothing less comparable. A guinea-pig inoculated with diphtheria dies in one to two days, and autopsy reveals constant lesions which are never found in man. The evolution and lesions likewise differ in rabbits and dogs. This is because diphtheria in man—exception being made of the laryngeal type and malignant form which are rare—is

usually a benign process. Normal human diphtheria, a benign infection with attenuated intoxication, is dangerous because of the late accidents which may ensue.

Now, what is the pathogenesis of these late complications? It is an unquestioned fact that up to the present they have never been produced in animals. Loeffler, Roux, and Yersin have shown that with the soluble toxin early paralyses may be produced, but not late paralyses, the typical diphtheritic form, and Loeffler so well understood the distance separating clinical facts from experimental ones that he hesitated to admit the paralytic nature of the accidents he observed. It is nevertheless true that the soluble toxin is capable of producing nervous accidents and it is more logical to regard it as a cause of later paralysis. By what mechanism? It would seem that the action of the fixed toxin should be made to intervene. Without prejudice to the intimate reason of the phenomenon, one fact appears certain, namely, that in animals a small quantity of active toxin or a larger amount of attenuated toxin is capable of causing late accidents and that in man an attenuated injection may give rise to late complications. Another certain fact is that in animals a sufficient quantity of the same active toxin will kill quickly and in man a serious infection will give rise to early accidents of variable gravity.

The first order of phenomena is in contradiction to our present ideas of acquired immunity, if it be admitted that there is only a simple diffusion of the toxin without previous fixation. On the other hand, the theory admitting that the tardy accidents are the result of a progressive accumulation of the toxin in the nervous centers produced by pathogenic organisms cannot be accepted, since the same phenomena follow a single injection of soluble toxin only. Therefore, it is more logical to admit that the soluble toxin becomes in the first place fixed on certain bodies and later on it differs secondarily, being freed by the dissociation of these bodies. In all infections, the toxin produced should also in the first place saturate these bodies for which it has an affinity. Saturation having been completed, the toxin then diffuses through the organism causing immediate symptoms, while the fixed toxin becomes freed much later, acting after all evidence of infection and local intoxication have disappeared.

In favor of this hypothesis may be invoked the appearance of the late complications of diphtheria in man and the late accidents observed in animals after injections of attenuated toxin or minute quantities of virulent toxin (Roux, Yersin). The same phenomena are provoked by lipoids and even various tissues that have been in contact with the soluble toxin, and then there is the well-known notion of the power of absorption of the soluble toxin to lipoids in general. It is probable that the accidents observed by Ménard (Thesis, Paris, 1913), following injection of diphtheritic lipoids was due to the persistency of a fixed but attenuated soluble toxin in these lipoids.

It is likewise probable that the phenomena observed by Rist, have the same origin, because he killed the bacilli with chloroform which only attenuates the virulence of the toxin without destroying it, while the preventive injection of antitoxic serum was insufficient to neutralize all the toxin adherent to the lipoids.

The part played by the fixation of the soluble toxin requires further research. The actions belonging to the constitutive poisons are, on the other hand, well established, so that it can be said that the increasing action of the lipoids of the diphtheria bacillus is constant and intense. No matter how they are introduced into the body they set up a rapid necrosis of the parts in which they sojourn, with a fibrinous exudate, while their influence in the production of local diphtheritic lesions has been amply demonstrated.

DIPHTHERIA ANTISERUM IN MUMPS.

THAT preventive vaccines occasionally appear to prevent or cure diseases quite unlike the specific affection aimed at has long been known but usually regarded as a case of *propter hoc*. In the Surgeon General's Catalogue may be found numerous reports of cure of whooping cough and various other maladies as a result of vaccination against smallpox. Diphtheria antiserum has often seemed to influence favorably various acute infectious diseases, but so far as known the first prophylactic action to be taken seriously is the alleged action of diphtheria antiserum in preventing the orchitic metastasis of ordinary epidemic parotitis. The subject goes back to 1917 when in the midst of an epidemic of mumps an Italian physician, Salvaneschi, chanced to inject this serum in a case of incipient metastasis in both testicles. A favorable reaction having promptly set in the doctor began to use the serum as a preventive. The fact that of 26 patients not one developed orchitis was with some reason regarded as more than a coincidence.

In *La Presse Médicale* for December 22, 1920, xxviii, 94, Bonnamour and Bardin give a considerable history of our recent and older knowledge of the frequency of orchitis in mumps. This ratio has varied in the past century or more from 10 to 25 per cent. A liberal estimate of the average would be 20 per cent. and of this number half are followed by atrophy of the testicles involved. The authors during 1918 had the opportunity of testing the new resource in an epidemic of mumps in young men of about the age period 19-21. There were 65 typical cases in each of which the antiserum was injected. The dose injected was 20 c.c. But in five of the patients the complication was under way on the first visit, and of the remaining sixty, three of the patients developed orchitis despite the injections. Seven cases seen since developed no orchitis after injection, which raises the ratio to 64:3, or less than 5 per cent. Further reports will be awaited with interest.

PROPHYLAXIS OF EPIDEMIC ENCEPHALITIS.

It is apparently time to agitate the question of the prophylaxis of this affection, which must persist in latent, sporadic form among germ carriers until the time is ripe for new outbreaks. The limited incidence should not blind us to the possibility of a much wider spread, which will be comparable to the maximum epidemic incidence of epidemic meningitis and acute poliomyelitis; the high mortality of which is alone a sufficient stimulus to devise a prophylaxis. At a recent session of the Paris Academy of Medicine (*Le Bulletin Médical*, March 9-12, 1921, xxxv, 11) Netter brought up the subject of the etiology and prophylaxis of this affection. It can occur anywhere in the world and probably has always existed, and without giving his data the author states that it probably was known in antiquity and the Middle Ages, even although the first authentic epidemic goes back only to 1712. The present outbreak should be about due to disappear as it has been with us for several years. The infection, however, will not become extinct, for now and then there will doubtless occur a sporadic case without any tendency to contagion or cumulation. That it spreads entirely from man to man during the epidemic phase the author is convinced—there is in fact no other method of propagation. The diffusion passes through some individuals who act as immune carriers. With such low diffusibility any question of wholesale prophylaxis seems out of the question. In any suspicious case, sporadic or epidemic, whether of a victim or of an alleged carrier, we should isolate the patient until the nasal fossæ can be sterilized. The period of quarantine must necessarily be purely arbitrary for we do not know when the subject becomes harmless to his entourage. Neither do we know just how strict must be the degree of isolation nor the part in contagion played by such possible fomites as the bedding, curtains, etc., though probably the latter source is negligible.

EXPERIMENTAL YELLOW FEVER.

Dr. M. G. LEBREDO, Chief of the Epidemiological Division of the Health Department at Havana obtained last April, through the courtesy of Dr. Noguchi, two cultures of the spirillum found by the latter at Merida in a subject with yellow fever. He began to experiment along several lines, including animal inoculation and mosquito transmission (*Revista de medicina y cirugía de la Habana*, February 25, 1921, xxvi, 4). The present article deals only with the author's exhaustive experiments in transmitting the disease to guinea pigs. He found no natural immunity—not an animal of the large number inoculated proved entirely refractory; but the animals could be made refractory by immunization. Relative resistance was in proportion to size and age. Every inoculated animal developed fever and jaundice and all exhibited icterus and focal hemorrhages in the large viscera. There were no free hemorrhages into the digestive tract and no macroscopic evidence of fatty degeneration. Virulence of the germ was clearly enhanced by passage from animal to animal. The *Leptospira icteroides* was cultivated in a semi-solid agar-Ringer medium of a known alkalinity, using the serum of man, the guinea pig, or the rabbit. One culture retained its

virulence for 7 months and 3 days. The author found that a lead foil covering sufficed for protection. The microorganisms were found in the blood in nearly 80 per cent. of all cases examined. In emulsions of liver and kidney from infected animals, they were found in 82 per cent. of all cases, but even in the remainder the disease was readily transmissible.

News of the Week.

New York Scores Low Infant Mortality Rate.—The records of the New York Health Department shows that for the first fourteen weeks of 1921 the infant mortality rate was 80 per 1,000 children born as against 112 for the corresponding period of last year. This represents a saving of 1,132 infant lives. In commenting upon this reduction the Health Department can assign no definite cause, but suggests the possibility that the mild winter which resulted in better ventilation of premises and in children being out of doors a greater part of the time may have been a factor, and also that better food, better clothing, and the more general dissemination of educational propaganda in regard to hygiene may be responsible.

Florida Physicians Want Composite Medical Examining Board.—The Florida Midland Medical Society, at its meeting in St. Petersburg, April 13, passed resolutions calling attention to the deplorable situation arising from the existence of five separate medical examining boards and putting itself on record as opposing the present system of medical licensing in that State. The resolutions endorsed Governor Hardee's utterances in his message to the Legislature for a more effective method of licensing physicians in the State by passing a composite medical examining act which will include the now various boards, and which will prevent irregularities in the issuing of licenses such as are alleged to have occurred under the present system.

The Right to Prescribe Alcohol.—The following resolutions were presented by Dr. John P. Davin and seconded by Dr. Bert B. Diamond at the meeting of the Medical Society of the County of New York April 25, 1921, and referred to the Comitia Minora for action by the Society at the meeting of May 23. *Whereas*, Under the Eighteenth amendment to the Constitution of the United States and under the National Prohibition Act, the use of alcohol as a medicinal agent by the Medical Profession is distinctly recognized and allowed. *And Whereas* in accordance with the demand of the Board of Temperance, Prohibition and Public Morals of the Methodist Church, the Anti-Saloon League, and the Political Promoters of Prohibition Propaganda at Washington, the Amendment to the Volstead Act is about to be proposed to prevent the manufacture, sale, and prescribing of malt alcoholic beverages long used medicinally by physicians, thus nullifying the right of the physician under existing law to prescribe alcohol by denying its use in this form. *And Whereas*, up to this time, there has not been presented to Congress, while making these Laws, any scientific or authoritative exposition of the principles underlying the use of alcohol in medicine upon which to base these measures. *Therefore, be it resolved* that the Medical Society of the

County of New York respectfully petition the Congress to defer action on the Amendment now demanded by the religious, lay, and political bodies mentioned above until the medical profession has had an opportunity to pass upon this measure in a scientific session at the meeting of the American Medical Association soon to be held at Boston.

Missouri Amends Medical College Bill.—Governor Hyde has signed the Ralph bill amending the present law affecting medical colleges in that State in the face of the determined opposition of the Missouri State Medical Society. The bill amends the present State law by striking out the word "reputable" and substituting therefor "regularly chartered" preceding medical colleges. The bill was introduced and supported by medical colleges not now recognized by the State Board of Examiners. In signing the bill Governor Hyde issued a statement expressing the opinion that the bill safeguarded the interests of the people of the State through the State Board of Medical Examiners.

General Ireland Entertains British Physicians.—Surgeon-General Ireland gave a luncheon, on April 23, at the Army and Navy Club in Washington, in honor of Major-General Sir Wilmot Harrington, physician in ordinary to his majesty the king, consulting physician to St. Bartholomew's Hospital, and vice-chancellor of the University of London, and Sir Walter Fletcher, secretary of the Medical Research Council, and senior demonstrator in physiology of Cambridge University. They are making a tour of inspection and study of various medical and scientific institutions in the United States and Canada. Among the guests were Admiral Stitt, General Hugh Cumming, General W. D. McCaw, General C. E. Sawyer, Dr. Haven Emerson, Colonel James D. Glenan, Colonel M. A. DeLaney, and Colonel Joseph F. Siler.

Grip Epidemic in France Decreasing.—A despatch from Paris under date of April 29 states that the epidemic of gripe in French camps that has threatened to assume serious proportions for some time seems to be subsiding.

Alcoholic Cases increase in Kings County.—An increase of nearly 120 per cent. in the number of alcoholic cases admitted to the Kings County Hospital within the last nine months has been reported by Dr. Mortimer D. Jones, medical superintendent, to Bird S. Coler, Commissioner of the Department of Public Welfare. The report states that 650 persons were admitted to the alcoholic wards during the nine months ending April 1, as against 299 for the corresponding period in 1919-1920. The cases have become much more acute in character.

Merger of Medical Societies.—The Northwestern Medical and Surgical Society and the Lenox Medical Society of this city have united and the new society will henceforth be known as the Northwestern-Lenox Medical and Surgical Society.

Beth David Hospital Needs Funds.—The eighth annual meeting of the Board of Directors of Beth David Hospital, New York, was held April 26, when it was announced that the new building at 113th Street and Lexington Avenue is nearing completion. The building fund is still lacking

about \$140,000. The annual report of the hospital shows that during the past year 561 charity patients were cared for at a cost of \$31,742. The number of patients admitted was 1,569, while 12,166 received treatment in the dispensary.

American Surgeons Honored.—The Council of the Royal College of Surgeons of Ireland, on April 26, resolved to confer Honorary Fellowship on the following American Surgeons: Drs. William and Charles Mayo of Rochester, Minn.; Dr. George Emerson Brewer of New York; Dr. George W. Crile of Cleveland; Drs. Richard H. Hartz and W. W. Keen of Philadelphia, and Dr. A. J. Oschner of Chicago. The ceremony of conferring the honors will take place in the autumn.

Honored on 99th Birthday.—A dinner in celebration of the ninety-ninth birthday of Dr. Stephen Smith of New York City was given by the One Hundred Year Club at the Cooper Carleton Club, Chicago, on the evening of April 29. Dr. Smith was not present but sent his greetings by telegraph.

Charitable Bequests.—Among the legacies provided for by the will of the late Mrs. Julia Seligman of New York are the following: Mount Sinai Hospital, New York, \$10,000; Hebrew Orphan Asylum, United Hebrew Charities, and Tribune Fresh Air Fund, each \$5,000; St. John's Guild, \$3,000; Hospital for Deformities and Joint Diseases, New York Society for the Relief of Ruptured and Crippled, Manhattan Eye, Ear and Throat Hospital, Bellevue Hospital, and the Montefiore Home to be used in its sanitarium at Bedford, each \$2,500; Henry Street Settlement and the Monmouth Memorial Hospital, Long Branch, N. J., each \$2,000. The Post-Graduate Medical School and Hospital receives a bequest of \$25,000 to be used in the department of diseases of the eye, and Mt. Sinai Hospital receives an equal sum for the establishment of beds, both bequests being in memory of the testator's mother, Carrie Wormser.

The American Association for Promoting Hygiene and Public Baths will hold its annual meeting in Brookline, Mass., on May 10 and 11, instead of in Philadelphia on October 8 and 9, as was previously announced.

Dr. George L. Behrens of Eldridge, has been appointed health officer of Winfield township, Iowa.

The Texas State Board of Medical Examiners, appointed by the Governor, April 16, 1921, is as follows: Dr. W. L. Crosthwait, Waco; Dr. S. L. Mayo, Belton; Dr. John T. Moore, Houston; Dr. H. C. Morrow, Austin; Dr. T. J. Crowe, Dallas; Dr. M. E. Daniel, Honey Grove; Dr. O. R. Morgan, Fort Worth; Dr. J. M. Watkin, Luling; Dr. J. F. Bailey, Waco; Dr. R. R. Norwood, Mineral Wells; Dr. George H. Sandifer, Austin.

Medical Society Elections.—THE TEXAS STATE BOARD OF HEALTH, recently appointed by the Governor, is composed of the following: Dr. F. M. Bledsoe, Port Arthur; Dr. M. P. Smart, Manor; Dr. Dickson G. Thompson, Waxahachie; Dr. Thomas S. Fisher, Dallas; Dr. M. M. Brown, Mexia; Dr. Nettie Klein, Texarkana.

THE HOMOEOPATHIC MEDICAL SOCIETY OF THE STATE OF NEW YORK, at its annual meeting held in Rochester, April 13, elected the following officers

for the ensuing year: *President*, Dr. Sprague Carlton, New York; *First Vice-President*, Dr. B. E. Kinne, Albany; *Second Vice-President*, Dr. J. H. Fobes, New York; *Third Vice-President*, Dr. W. W. Winans, Rochester; *Secretary*, Dr. Grace M. Kahrs, New York; *Treasurer*, Dr. Gertrude G. Mack, New York.

THE NEW YORK SURGICAL SOCIETY, at a meeting held in the New York Academy of Medicine, April 27, elected the following officers for the ensuing year: *President*, Dr. John A. Hartwell; *Vice-President*, Dr. Eugene H. Pool; *Secretary and Treasurer*, Dr. Seward Erdman.

THE WINDHAM COUNTY (CONN.) MEDICAL SOCIETY, at its annual meeting held in Putnam, April 21, elected the following officers for the ensuing year: *President*, Dr. F. E. Smith, Willimantic; *Vice-President*, Dr. G. T. LaMarche; *Secretary-Treasurer*, Dr. R. C. Paine, Thompson.

THE MERCER COUNTY (ILL.) MEDICAL SOCIETY, at its annual meeting in Aledo, April 12, elected the following officers for the ensuing year: *President*, Dr. L. R. Louis, North Henderson; *Vice-President*, Dr. Samuel Haley, Joy; *Secretary*, Dr. V. A. McClanahan, Viola.

THE ROCK ISLAND COUNTY (ILL.) MEDICAL SOCIETY, at its annual meeting held in Rock Island, April 12, 1921, elected the following officers for the ensuing year: *President*, Dr. B. J. Lachner, Rock Island; *First Vice-President*, Dr. F. J. Otis, Moline; *Second Vice-President*, Dr. A. E. Williams, Rock Island; *Secretary*, Dr. G. D. Hauberg, Moline; *Treasurer*, Dr. A. T. Leipold, Moline.

THE HARRISON COUNTY (MO.) MEDICAL ASSOCIATION, at its annual meeting held in Bethany, Mo., April 13, 1921, elected the following officers for the ensuing year: *President*, Dr. W. J. Harned; *Secretary*, Dr. W. W. Vandivert.

Obituary Notes.—Dr. HORACE C. MILLER of Rensselaer, N. Y., a graduate of Albany Medical College, in 1874, died following an operation in a local hospital, on April 11.

Dr. THOMAS P. CAMELON of Detroit, Mich., a graduate of Trinity Medical College, Toronto, in 1890, died of pneumonia, on April 7, at the age of fifty-seven years. During the late war he was a Major in the Medical Corps of the Army and served overseas.

Dr. CHARLES A. KODER, a graduate of Jefferson Medical College, Philadelphia, in 1882, died, following a stroke of apoplexy, on April 9, at the age of sixty years.

Dr. GEORGE B. GILBERT, a graduate of the University of Louisville Medical College, in 1901, died at his home in Louisville, Ky., on April 14, at the age of forty-five years.

Dr. JOHN G. JAY, a graduate of the University of Maryland School of Medicine, Baltimore, in 1871, and later associate professor of clinical surgery in this institution, died at his home in Baltimore, on April 1.

Dr. GEORGE LOREN MCCOY, a specialist in nervous and mental diseases, and founder of the Highlands Sanitarium, near Philadelphia, died at his home there, on April 6, at the age of forty-eight years. He was graduated from the Medical School of the University of Pennsylvania in 1896.

Dr. JOSEPH MILFORD MERCHANT of Warren, R. I.,

died on April 15 at the age of eighty-seven years. He was one of the oldest surviving graduates of Bowdoin College, having graduated from the Medical Department in 1858. During the Civil War he was Medical Officer at Fortress Monroe.

Dr. JOHN GALVIN MORRIS, a graduate of Harvard Medical School, in 1882, died at his home in South Boston, on April 14, at the age of sixty-five years. He was visiting physician to St. Elizabeth's Hospital, and a member of the American Medical Association.

Dr. LOUIS BRADFORD COUCH of Nyack, N. Y., a graduate of the New York Homeopathic Medical College, in 1874, died on April 20, at the age of sixty-nine years.

Dr. THOMAS ALEXANDER BUYS of Brooklyn, N. Y., a graduate of the New York Homeopathic Medical College, in 1897, died on April 19, at the age of fifty-one years.

Dr. MURRAY WISNER SEAGEARS of St. Augustine, Fla., died on April 19, at the age of forty-nine years. He was graduated from the College of Physicians and Surgeons, New York, in 1905, and was chief surgeon of the Florida East Coast Railway.

LIEUTENANT-COLONEL JOSEPH MORA MOSS, senior surgeon of the United States Public Health Service and assistant chief medical officer of the Federal Board of Vocational Education, died on April 23, at the age of fifty-four years. He was graduated from the University of California in 1894.

Dr. J. E. T. WELCH, a practitioner of Bushnell, N. C., and a Civil War veteran, died of heart failure, on April 12, at the age of seventy-four years.

Dr. SAMUEL L. KURTZ of Reading, Pa., died suddenly, on April 21, at the age of eighty-eight years. He was a graduate of Jefferson Medical College, in 1854, and served as a surgeon in the Civil War, being honorably discharged with the rank of Major. He was president of the Medical Society of the State of Pennsylvania in 1891.

Dr. B. HOWARD LAWSON, a graduate of the Cleveland (Ohio) University of Medicine and Surgery, in 1871, died suddenly at his home in Detroit, on April 15, at the age of ninety years. He was a member of the staff of Grace Hospital.

Dr. GEORGE GLANVILLE RUSK, a graduate of the University of Maryland School of Medicine, Baltimore, died from pneumonia on April 14, at the age of seventy-four years.

Dr. CORNELIUS S. ELDRIDGE, a graduate of the New York Homeopathic Medical College, in 1868, died at his home in Chicago, on April 19, at the age of eighty years.

Dr. SAMUEL L. DREINELIS, a graduate of the Hahnemann Medical College, Philadelphia, in 1906, died at his home in Reading, Pa., on April 13, at the age of seventy-three years.

Dr. RILLA GRAFTON HAY of Los Angeles, the first woman granted a license to practice medicine in California, died after a lingering illness, on April 7, at the age of seventy-one years. She was graduated from the University of Iowa College of Medicine in 1873.

Dr. S. M. GLADNEY, a graduate of the University of Louisville Medical Department, in 1877, died, after a lingering illness, at his home in Terrell, Tex., on April 13, at the age of sixty-seven years.

Dr. J. M. DALY, formerly of Nashville and Ark-

adelphia, and more recently of Little Rock, Ark., died suddenly of apoplexy on April 17 at the age of fifty-four years. He was graduated from the Medical Department of the University of Arkansas in 1895.

DR. A. P. DICKSON, a graduate of New York University Medical College, in 1878, died at his home in Raeford, at the age of seventy-one years.

DR. WILLIAM M. BARRON of Latrobe, Pa., a graduate of the University of Pittsburgh Medical School, in 1892, died on April 15, at the age of fifty-nine years.

DR. JACOB LONDONER of Brooklyn, a graduate of the University of Dorpat, in 1890, died suddenly of apoplexy at his home on April 27 at the age of fifty-eight years.

DR. WILLIAM E. LANDERS, formerly of New York City, died in a private sanitarium in Washington, D. C., on April 24, at the age of thirty-seven years. During the war he was a major in the army, serving a part of the time in the Fox Hills Hospital.

DR. CALIBORNE H. MANNAR of Rockville, Md., a graduate of Bellevue Hospital Medical College, in 1898, died suddenly at his home, on April 13, at the age of fifty-nine years.

DR. RICHARD S. KEELER, a graduate of the College of Physicians and Surgeons, Baltimore, in 1885, died of heart disease at his home in Butler, Pa., on April 17, at the age of fifty-seven years.

FRANCIS D. WRIGHT of St. Louis, Mo., a graduate of Rush Medical College, Chicago, died on April 18 at the age of sixty-five years.

DR. DAVID S. RAY of Cuba, Ill., a graduate of the College of Physicians, Keokuk, Iowa, in 1892, died suddenly, on April 16, at the age of sixty years.

a recognized school or be vouched for by three reputable physicians as to fitness and training and two citizens as to moral character. The applicant must also have been earning his or her living by the practice of massage for five years prior to the application; this is to prevent injustice to any who may have been trained by private instruction, either under any other good teacher or in institutions, when they had been deprived of the privilege of studying in a recognized school.

This law is good, except it makes no provision for the future, as there is not in New York City today a school or college that gives a full training to fit anyone to be a competent professional. How is the law to be respected and fulfilled unless Columbia University furnishes such a training or backs a properly conducted and equipped private enterprise? The answer will be, "We have no money and there is no demand by the medical profession." Both objections can be easily overcome, first by educating the people and the profession by lectures; there are capable men and women who will explain what massage and mechanical treatments are, when and why they may be more beneficial than medicine or the knife, and also what is equally important, when such treatments may be positively injurious.

Then the public and profession will demand a proper training for all those who dare to undertake the delicate and divine science of healing of suffering humanity.

There are already people ready and willing to cooperate with Columbia when that institution is ready to act and form a standardization for massotherapeutics.

MAUDE RAWLINS.

BROOKLYN, NEW YORK.

Correspondence.

THE TEACHING OF MASSAGE.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—For the last few years the subject of massage has been buffeted about, some condemning it wholesale, others acknowledging it has been efficacious in some instances; a few of these people realize that there are really some scientific reasons for good results, others feel that the benefits are psychological, and some believe that rubbing at the right time has oiled nature's machinery; others again, and I am sorry to say a very large number, look upon the whole matter as sheer charlatanism.

Are there not enough men in New York who are broad enough and reasonable enough to realize that anything that has stood the test and has survived longer than Christianity, must have a foundation of good? Does not the very fact that the term massage is used as generally as it is to-day, prove that there must be some reason why it has survived and also explain why it is used for illegitimate purposes.

As massotherapy so far has not been protected here by legislation or training, it is often hard to prove who is and who is not a scientifically trained massotherapist. At last a step has been taken in the right direction, for it is now necessary to be licensed in massage to practise in New York City, and the applicant must hold a diploma from

OUR LONDON LETTER.

(From Our Own Correspondent.)

LONDON, April 14, 1921.

Milk for Mothers.—The Ministry of Health have revoked the Milk Order, 1919, and the Local Authorities Milk Order, 1919. Local authorities in the future must obtain the sanction of the Minister to schemes for the supply of milk to expectant and nursing mothers and children. This step has been taken because it was found that many local authorities had incurred expenditure very greatly exceeding what was either necessary or desirable. Sanction will now only be given on conditions of which the following are examples: (1) Milk may be supplied at less than cost price in necessitous cases only to nursing mothers, expectant mothers in the last three months of pregnancy, and children up to three years of age, or, exceptionally, between three and five years of age. (2) The quantity must not ordinarily exceed one pint per day per person. In certain instances 1½ pints may be given. (3) The medical officer of health or the medical officer of a center must certify necessity. When the milk order of 1919 was brought into force it was stipulated that the distribution of milk below cost price, or gratuitously, should be restricted to necessitous cases. This restriction was revoked in deference to that section of opinion which considers that

maintenance should be provided by the State without reference to the recipient's actual needs, with the result that many persons obtained a supply who were neither necessitous nor deserving. Under the revised legislation the distribution of milk is now to be confined, to schemes approved by the Ministry of Health, so that the Government will regain control of this form of subsidy.

The Retirement of Dr. Addison From the Ministry of Health.—Dr. Addison has resigned the post of Minister of Health and has accepted a cabinet portfolio without office. When the Ministry of Health was established in this country it seemed that Dr. Addison was the logical first minister. He was a medical man but more of a politician, he therefore presumably understood both aspects of the situation. However, at the time when the Ministry of Health came into being the difficulties in the way of carrying out expensive schemes for the benefit of the health of the nation were immense. It was obvious that the health of the population was not so good as it might be. Even before the war this fact was patent and the war, of course, accentuated this condition of affairs. At the same time it was equally plain that a people already overburdened with taxes would be somewhat intolerant of schemes the execution of which involved the expenditure of very large sums of money. Perhaps it was the plans put forward by the Ministry of Health for the building of hygienic and sanitary houses in all parts of the country that prejudiced the public against the general policy of the Ministry. These plans were of a far-reaching character, almost grandiose in conception, and when it was recognized by the hard hit taxpayer, that owing to the cost of material and labor, a good deal of the expense would fall on him, like the proverbial worm, he turned. But there was another cause over and above the mistakes made by the Ministry, which brought about the fall, or rather, the resignation of its chief, and this was the criticisms leveled against the Ministry's policy, frequently unfair criticisms, by a section of the press. Dr. Addison as minister was made the chief target of these attacks, and while it must be confessed that sometimes he played into the hands of his opponents, many of the charges brought against the Ministry were colored and exaggerated, if not wholly unjustified. According to his critics nothing that Dr. Addison did was right nor could he do anything that was right. In the face of the innumerable difficulties that confronted Dr. Addison when he took office, his term has by no means been devoid of action calculated to advance the progress of preventive medicine, the object of the ministry. At least, a beginning has been made, a good deal of spade digging has been done. Although some of the schemes formulated appeared utopian, at any rate, it gave people furiously to think and this in itself was a good thing. On the whole, it is better to soar among the clouds than grovel in the earth, without imagination one never gets far.

It must also be borne in mind that the organizing, administrative brain of the ministry was lost when Sir Robert Morant died. Indeed, in many respects he was the main support of the

Ministry, and when this prop was taken away the structure was never again so firm. The new Minister of Health, Sir Alfred Mond, is not a medical man, but one of the most acute business men in this country, and it remains to be seen whether his acumen will succeed in reducing the Ministry of Health to a business basis, and in carrying into execution a few of the most pending schemes evolved from the brains of Dr. Addison and his colleagues.

A German Manifesto on Vitamines.—The following is in a recent issue of the official German Health Publications and is published in the *Lancet*, April 9, 1921: "The coming months threaten us with grave food difficulties, similar to those of the winter and spring of 1917. Lengthy research has established the fact that the ill consequences of insufficient diet depend not only on the lack of total quantity, but, in much higher degree than was once thought, on the lack of certain accessory substances, vitamins, essential alike in adults and children to the well-being of the body, but distributed very unevenly in the usual foodstuffs. Added in sufficient amount these substances can, to a certain extent, compensate for insufficient total quantity of food. Conversely in their absence, even the most abundant diet is not able to ward off English disease (rickets), bone softening, watery swellings (edema), nutritional changes in the blood and nerves, loss of resistance to tubercle and other diseases. Unfortunately, a great part of the foodstuffs which contain in high degree these important accessory substances—e.g. fresh milk, best dried milk, butter, whole-milk cheese, cream, fresh meat, liver, kidneys, heart, brain of animals, fat fish, eggs, dripping, and lard are hard to obtain and very costly. Their lack, however, can be made good by cheaper material. Emphasis should, therefore, be laid on such foodstuffs of which the most important are: codliver oil, wheat (whole meal, including the bran, as in Graham bread); the germ of grain especially of wheat, germinating grain, as in the production of malt; peas, beans, lentils, soya beans, also in dry form; all forms of fresh green leaves, all kinds of cabbage and spinach, provided that they are only steamed and not brought to the boil. According to recent research the stinging nettle provides a tasty dish rich in vitamins. Any kind of salad, varieties of lettuce at the head—fruits, nuts, dessert fruits, lemons and lemon juice. As vitamin-rich fruits apples are specially to be noted. Oranges are rich in vitamin. Fresh yeast and its preparations and malt extract in certain forms has been found to contain vitamin. The substances in question pass from the expectant mother to the fetus, and from the nursing mother into her milk. When these substances are lacking the bodies of mother and child suffer even with abundant food." For detailed information ask your doctor. The signatories to the manifesto are Professors V. Bergmann, Ellingen Embden, v. Noorden, Quincke, and Strasburger, members of the Faculty of Medicine at Frankfurt University, and Hr. Schlosser, president of the City Health Department.

Reference is made to this quotation, be-

cause it shows how great attention is paid nowadays to the importance of the presence of a sufficiency of the vitamin element in the diet. The great cost of food renders it necessary that the mass of the population should be taught to choose cheap food which contains enough of the accessory food factors to adequately nourish. In this country few people know anything as to the best kinds of food to eat. For example, in London restaurants it is difficult to procure brown or Graham bread, the majority greatly prefer white bread made from highly milled flour. It is the same with several articles of diet. Educational propaganda here is required to teach the people what to eat. Dr. Harry Campbell preaches the doctrine of diet in and out of season, and gives advice with regard to the most nourishing forms of cheap food. More teachers of his authority are needed if the Englishman is ever to learn that there are not a few inexpensive foods, which he despises, but which contain the essential vitamin element and are palatable.

British Venereal Disease Commission to the Far East.—At a joint meeting of the Sheffield Medico-Chirurgical Society and British Medical Association, held on March 24 in Sheffield, the venereal disease commission to the Far East was discussed. Dr. Rupert Hallam gave a short account of his journey round the world as the medical member of a commission which was dispatched to the Far East by the National Council for Combating Venereal Diseases. The commission first visited New York, arriving there early in November, 1920, where Dr. Hallam had the opportunity of seeing several of the well-known skin and venereal clinics. He pointed out that the majority of patients in New York pay for their treatment, although necessitous patients are able to obtain free treatment. Compulsory notification and treatment of venereal disease has been in force in New York for more than a year, and according to Dr. Hallam the consensus of opinion is that this has not acted as a deterrent to patients to seek treatment.

The commissioner next visited the New York State Laboratory at Albany and was considerably impressed with all that he saw there. The commission then journeyed across Canada, making brief stays at Toronto, Winnipeg, Regina, and Victoria, where meetings were held under the auspices of the Canadian Council for Combating Venereal Disease. In Japan useful information was obtained from the officials of the Government Health Department. At the invitation of the Shanghai Municipal Council the commission conducted a campaign of public enlightenment in that city, and Dr. Hallam gave a series of lectures and demonstrations to the medical practitioners in the diagnosis and treatment of venereal disease. The incidence of both syphilis and gonorrhea among the Chinese in the seaport towns is very high, and before the visit of the commission there was no treatment by modern methods available for them. The commission conducted a similar campaign at Hong-Kong, Singapore, and Colombo, and in each of these ports recommended that the free diagnosis and treatment of venereal disease should be provided.

4. Fecal Units and Intestinal Rate. Francis Lowell Burnett.

1. The Rationale of Forcing Fluids.—George Gilbert Smith considers it worth while to gather certain data bearing on the question of the forcing of fluids in patients with deficient urinary excretion, inasmuch as the results, both in the increase in the amount of urine and in the improvement in the general condition of the patient, have been so striking. Accordingly, he reviews briefly the physiology of the kidney, and discusses the efficiency of the kidney as a means of ridding the body of waste products, the factors involved, and the three ways of increasing the fluid content of the body (ingestion into the alimentary tract, subcutaneous injection of normal saline solution, and intravenous injection of the same). He then discusses the indications for forcing fluids, as in the presence of acidosis after etherization. Even in a patient with healthy kidneys one often finds the signs of renal insufficiency, *i. e.* soft distention, dry tongue, and nausea. Being nauseated, the patient cannot take water, thereby increasing the symptoms. One subcutaneous injection of a liter of normal salt solution will usually suffice to break the vicious circle. It is far better, however, to anticipate the lack of fluids by: (1) forcing fluids until one or two hours before operation; (2) immediately after operation giving either a subcutaneous infusion or three pints of tap water by rectum. The latter, if given before the patient comes out of ether, will usually be retained. After that, the Murphy drip may be used or tap water may be given rectally, eight ounces every six hours. If normal kidneys will react in this way to a lack of fluid, how much more seriously affected are damaged kidneys, particularly kidneys of urinary retention, whose ability to excrete has been taken away at least temporarily by long-continued back pressure. With a sound heart and fairly good kidneys, an intake of 200 ounces every 24 hours is not at all excessive.

2. Albumin, Lymphocytic Cells and Tubercle Bacilli in the Sputa.—Kumpei Takeuchi reviews the opinions of others, then states his own. The point of view held that attributes albumin directly to tuberculosis is naturally annulled by the fact that albumin is often found in the sputa of various cases of other than phthisis. And it does not conform to facts to diagnose a case as tuberculous by the quantitative difference of the albumin in sputum only. Therefore, one cannot but conclude that the existence of the albumin alone in the sputum is insignificant from the diagnostic point of view, even though it is conspicuous in quantity. But if a large number of leucocytic cells (above thirty per cent.) are found together with albumin in sputum, then for the first time one can suspect the case to be

tuberculous. It is also the same in the following cases: In the examination of the albumin in urine one cannot diagnose a case to be nephritis, even though albumin is positive, but one knows the case to be nephritis if casts are found, and can diagnose bladder troubles when a large quantity of the bladder epithelium is found. And in the examination of the cerebrospinal fluid, the albuminous preponderance does not suffice by itself to make an authentic diagnosis, but if lymphocytic cells are found the suspicion of tuberculosis is intensified, and if the so-called four reactions are present one may well recognize with authenticity a case as progressive paralysis. With these views in mind the writer determined to ascertain the relation of tubercle bacilli, albumin, lymphocytic and eosinophil cells in sputa. He examined the sputa sent to the Hygienic Investigation Committee attached to the Hygienic Association, Nihonbashi, Tokyo. From these examinations he concludes that tubercle bacilli, albuminoreaction, and the preponderance of lymphocytic cells in sputa maintain a parallelism. Eosinophil cells also go parallel with these three to a certain degree.

13. Who is Responsible for the Sponge Count?—J. W. Kennedy answers this question by holding that from the doorknob on, everything pertaining to the operation comes directly under the supervision of the operator and he is responsible for all. There is no teaching so reprehensible, so void of all that is manly, so negative of sacred duty, so impotent in strong teaching principles, as to hold a nurse or surgical associate responsible for the sponge count.

15. Fractures.—H. B. Pritchard holds that a study of fractures should be based on end results as regards the anatomical, the functional and the economic conditions. A study made on that basis will break one away from the time honored teaching of the disability caused by fracture as measured by the period of time necessary for union. The aftertreatment of fractures has a demand upon the surgeon as has the uniting of the broken ends, and it is a large item in the treatment of fractures. The open operation is seldom justifiable, and will probably be used less rather than more as time goes on. This is because of the ease with which infection gains entrance in an open operation fracture and the difficulty with which it is prevented. Because war surgery developed some new methods of treating fractures and reestablished some older discarded methods is not of itself sufficient reason for continuing their use. The difference between the war and civil fractures must be considered, and as a result of that the best treatment can be devised for each. Non-union occurs in these days because of some inherent condition in the individual or of the fracture, and not because of insufficient splinting. For this reason the writer makes the plea that more frequent inspections of the limbs be made, and that early massage and passive movements be started.

8. The Salem, Ohio, Typhoid Epidemic: A Clinical Report. William Hall Dunn.
9. The Significance of Unequal Pupils.—Earl B. Brooks holds that, with the exclusion of eye disease and refractive errors, unequal pupils are always pathologic. The width of the pupil and its reaction any given time are the result of the constant antagonism between the contracting fiber of the third nerve, and dilating fibers of the cervical sympathetic. The determination of whether or not one has to deal with an irritative or paralytic lesion will help materially in the recognition and proper interpretation of unequal pupils in any given case. In contusion of the eyeball, besides the concussion, small lacerations and extravasation of blood into the iris muscles account for some of the pupil changes. In head injuries, the dilated

pupil corresponds to the side of increased pressure.

5. Antisyphilitic Therapy. A Comparative Study of Some Intensive Methods.—Louis Chargin found it necessary, for the proper conduct of this study, to choose: (a) Patients with recent infections, and only such as presented the early cutaneous manifestations of the disease. (b) Cases in which the Wassermann reaction had already become strongly positive (from three to four plus). This served the double purpose of corroborating the diagnosis, and as the criterion of the efficacy of the various plans of treatment with which he experimented. No case in which antisyphilitic treatment had been given before was included, in order that the question of prior treatment should not enter as a factor. The study included 106 cases, all of which met the conditions enumerated. The study demonstrated that 80 per cent. of the early syphilitic patients treated by the modern intensive methods became negative by the tenth week; 93 per cent. by the sixteenth week, and 100 per cent. by the twentieth week. As a general rule, it may be stated that the more recent the infection at the time intensive treatment is begun, the sooner the Wassermann reaction becomes negative. To this there were notable exceptions. Since the clinical and serologic results are practically the same by all methods described in this paper, and since the margin of safety is in favor of the less intensive plan, it would seem justifiable to conclude that the less intensive plan should be favored as the method of choice in the treatment of syphilis.

6. Apex, Hilum and Lower Lobe Lesions of Tuberculosis in Childhood: Their Relative Frequency.—William R. Vis deals in this paper with clinical rather than pathological findings. He discusses not where the initial lesion is found, but where it can first be detected by clinical methods of examination. From the evidence presented it appears probable that in the young child there is a physiologic cause which predisposes the hilum of the lungs to tuberculous infection, namely, the low resistance to tubercle toxin and the consequently greater dependence on the lymphatic system to combat the infection. On the other hand, one has an anatomic cause for the comparative immunity to infection of the lung apex, in the greater respiratory excursion and freer circulation in the child as compared with the adult. In accordance with these phenomena, one finds that in the child tuberculosis may be diagnosed most frequently at the hilum, the apex next in frequency, and the base least often.

7. Tuberculosis in Germany. E. G. Glover.
8. The Treatment of Infectious Diseases by Leucocytolysis Produced by Roentgenization of the Spleen.—Ivan I. Manoukhin makes the clinical application of the theory previously proposed by him regarding leucocytolysis. By direct experiments he proved that an organism combats infection mainly by means of the breaking up of its leucocytes. If in many acute infectious diseases there is an increase in the number of leucocytes in the blood, he regards this phenomenon as preparatory to their subsequent breaking up. The organism can cure itself only when the specific anti-substances produced by the leucocytes have come out from them and filled the blood plasma, as a result of the leucocytolysis. This process is produced in the blood by special soluble ferments entering into it, which he called "leucocytolysins," and leucocytolysis, in those cases when it precedes leucocytolysis, is produced by soluble ferments, whose properties are opposed to those of the leucocytolysins, and which he called "anti-leucocytolysins." Later, he succeeded in proving that leucocytolysins are produced by the spleen,

and anti-leucocytolysins by the liver. The correctness of this theory was established by animal experiments. He infected monkeys and guinea-pigs with human tuberculosis, and artificially stimulated in them the activity of the spleen so that leucocytolysins would appear in the blood and that the leucocytolysis caused by them would exercise its curative effect. The stimulation of the activity of the spleen was carried out by radiating the organ with small doses of Roentgen rays. The method is now being widely applied to human beings for curative purposes. The writer discusses briefly its application in pulmonary tuberculosis, typhoid fever, tetanus, and other conditions.

Vascular Change During Uterine Involution: A Study of the Condition of the Arteries in a Uterus Removed Twenty-four Days after Delivery.—Geoffrey Evans relates that the organ was placed in formol-saline, and at a later date parts of it were removed for section, and the sections prepared. The sections showed the usual changes in the vessel walls characteristic of normal arterial involution. The most striking changes occurred in the intima; there was a cellular proliferation and hyaline swelling of the subendothelial layer, together with a swelling and splitting of the internal elastic lamina. In the media there is the appearance of a granular atrophy of the muscle fibers and a hyaline swelling of the intermuscular connective tissue fibrils.

2. Further Observations on the Etiology of Eclampsia and the Pre-Eclamptic State.—James Young and Douglas A. Miller present, in this paper, confirmation of an explanation of eclampsia published by one of them in 1914. It is based on a study, carried out at the Royal Maternity Hospital, Edinburgh, of 40 cases of toxemia and associated conditions. The original investigations professed to show that the eclamptic and the pre-eclamptic toxemia is dependent on a placental necrosis, and they culminated in the experimental reproduction in animals of a disease closely simulating the classical picture of eclampsia. The first observations were concerned with a study of the pathology and with experiment. In this contribution they give a third link of proof—the clinical. From this clinical study they formulated the following summary: 1. Eclampsia and pre-eclamptic toxemia are due to the products of the early degeneration of a piece of placenta whose blood supply has been interfered with. 2. Infarction of the placenta may be due to mechanical detachment of the organ from the uterine wall—for example, in placenta previa and in some cases of accidental hemorrhage. In other cases it is due to thrombosis; this is the factor operating in most cases of eclampsia. 3. Where time is allowed for the elaboration of toxic elements from the detached placenta toxemia develops. In concealed accidental hemorrhage, therefore, toxemia is conspicuous. Absorption of placental poisons only occurs if and while part of the placenta remains attached to the uterine wall. 4. Toxemia occasionally accompanies placenta previa for the same reasons. 5. The toxemia develops after the hemorrhage; it is therefore not the cause of the bleeding in accidental hemorrhage. 6. The major symptoms of eclampsia are probably due to the flooding of the mother's system with the breaking-down products of liver cells (and perhaps of other tissues), which were killed some hours or days previously by the placental poison. Compare the interval that elapses before the development of symptoms in phosphorus poisoning, etc. A consideration of this sort accounts for the occasional occurrence of postpartum seizures. 7. Recent investigations (Quénu, Delbet, etc.) support by analogy this conception of eclampsia. These observers have shown that the early disintegration products of muscle are

toxic. The injection of these substances into an animal may kill at once. On the other hand, the lethal effect may be delayed for some time, in which case it is due to degeneration of the liver and suprarenal glands. The changes induced in the liver in such a toxemia resemble those found in the liver in eclampsia.

3. Cardiac Peristalsis and Mitral Stenosis.—D. W. Samways holds that there is considerable evidence to show that the contraction of the auricle normally overlaps that of the ventricle, lasting probably till the moment of opening of the aortic valves. In cases of mitral stenosis this overlapping tends to be still further prolonged, invading there for the expulsive portion of the ventricular systole. The ventricle could not prevent the auricle sending its residual blood into it, if their contractions overlapped, because at that time the auricle, being small, would have few units of area of blood to contract on, and a thickened mass of muscle to exert the necessary pressure, whereas the ventricle would be in exactly the reverse position at the time. In cases where the mitral was stenosed the auricle would be further helped by hypertrophy of its walls and thinning of those of the ventricle. The murmur of mitral stenosis ("presystolic") goes up to and into ventricular systolic time because the blood flow does likewise. The murmur is "crescendo" in character because the auricle can exert an ever-increasing pressure on its contents as it contracts. Theoretically the pressure can increase inversely as the cube of the decrease in diameter. Regurgitation through an incompetent mitral orifice is prevented, probably for years, by the contraction of the auricle behind that orifice during the expulsive portion of the ventricular systole. The presystolic murmur is replaced by a systolic murmur when the auricle cannot decrease its size in time to become a sufficiently small chamber to defeat the oncoming of the intraventricular resistance, but on the contrary is defeated by it. This will allow regurgitation, the auricle will speedily dilate, fibrillate, and compensation will break down. Temporary recovery by rest or bleeding will probably mean that the auricle becomes again, for a short time, master of the situation.

1. Dyspepsia and Malassimilation in Children.—Hector Charles Cameron, discussing the causes of gastrointestinal disturbances in infants, holds that the special liability of the young child to gastrointestinal disturbances depends not only upon his high demand for food and the strain thereby imposed upon digestion, but also upon two further characteristic features of infancy—a low immunity against catarrhal infections of all sorts, and a highly sensitive and uncontrolled nervous system. These three factors act and react with each other in the most intricate way. A faulty diet, and especially a diet which is deficient in fat, produces a lowering of immunity against infection; infection is accompanied by a fall in the tolerance for all food, and especially in the tolerance for fat. Crying and emotional display increase greatly the heat lost from the body, the expenditure of energy, and the need for food, while inhibiting digestion as surely in infants as in adults. The infective conditions which cause diarrhea and vomiting in infants are, comparatively, seldom intestinal, but much more often non-intestinal, or parenteral. The accompanying diarrhea and vomiting may persist throughout the illness, and may be so prominent as altogether to obscure the underlying infection. Gastrointestinal disturbance symptomatic of parenteral infection is probably that which is most frequently met with, especially in breast-fed children. It

is characterized by the suddenness of its onset, often in the midst of perfect health. In this it contrasts with the onset, usually gradual, of primary dyspepsia of purely alimentary origin. Nor does it tend to follow upon an increase in the amount or a change in the character of the diet. The temperature is usually raised higher than is the rule in primary dyspepsia. It is important to recognize the underlying element of infection, because in this symptomatic dyspepsia nothing is to be gained, as a rule, by radical alteration in the character of the diet. Primary dyspepsia may be produced by sheer overfeeding, especially by excess of fat or sugar. Often, however, one is driven to the conclusion that the disturbance is dependent upon an individual idiosyncrasy—that in certain children the power of dealing with sugar, or starch or fat is, relatively, low and easily overstepped. When the child fails to digest and thrive upon the ordinary milk mixture suitable for his age, that is to say, upon the standard artificial diet of health, the treatment consists in the appropriate modification of the diet in the direction indicated by the symptoms. Severe dyspepsia in infants may be the result of sleeplessness, restlessness, crying, and emotional display. Treatment is successful only when it controls the underlying cause—the nervous unrest. To reduce the size of the feeds, to dilute them, to prescribe a twenty-four hours' fast or a purge—the usual methods with primary dyspepsia, are capable of doing a great deal of harm and greatly increasing the severity of all symptoms. In older children a common form of dyspepsia is consequent upon nutritional defect, with amyotonia, vasomotor disturbances, and nervous exhaustion. Treatment must, in great part, be concerned with the education of the child, with its mental, moral, and physical discipline. The lax, timid posture noted in these cases is an expression of a temperamental fault which can be corrected only by educational means. Massage, physical exercises, drill, dancing, eurythmics and the rest, all play an important part. The personnel of the child's immediate environment is important.

9. Static Conditions of the Lower Extremities as Influenced by Circulatory Disturbances.—Thomas Madden Foley bases this communication on the analysis of the findings in one hundred patients who obtained only partial relief from treatment, his object being to discover, if possible, the most frequent cause of pains in the lower extremities. In practically all of this group the pains were described as occurring not in the joints, but rather in the regions between the joints. A fairly large number complained of discomfort or actual pain on the inside of the thighs and legs, as well as on the anterior aspects, regions not usually affected by the wellknown static disturbances. Examination showed that in 50 per cent. of the patients a hard swelling was noticed over the lower aspect of the leg, especially about the region of the internal malleolus. Soft or doughy edema about the ankle and dorsum of the foot was the exception rather than the rule. The left leg was affected more frequently than the right, and men and women were about equally affected. In point of nationality the Jewish race predominated out of proportion to the total of patients treated. In only 10 per cent. could the blood pressure be considered above normal. No atrophy was apparent in any of these cases. Thickening was rather the rule. In 75 per cent.

of the cases the feet were distinctly pronated, 90 per cent. had some kind of mottling due to a network of small superficial veins. Superficial veins in many of these cases were observed grouped in a rosette form similar to the caput Medusae seen on the abdomen which becomes distended in portal obstruction. Every one of these patients complained of fatigue and pain on exertion, the pain being of the type described. Practically all observed that pain was relieved by elevating the leg. Seventy per cent. had distinct flat foot and 50 per cent. showed static strain of the internal lateral ligament of the knee. The findings are suggestive of obstruction or engorgement of the deeper veins. Appropriate systemic treatment for central circulatory disturbances is indicated.

1. A Plea for More Active Treatment of Weak Feet in Children.—Jacob Grossman, in connection with other preventive and curative measures, recommends exercises directed to the feet for children old enough to understand them. The following have been found efficient: 1. Tip-toe exercises: The patient places the limbs in the attitude of moderate inward rotation, raises the body on the toes to the extreme limit, the limbs being fully extended at the knees, then sinking slowly, resting the weight on the outer borders of the feet in marked varus, repeating about twenty to thirty times. 2. Walking in bare feet. 3. Walking on the fore part of the foot. 4. Grasping motions with the toes; exercises with foot weights. 5. Bicycling has also proved of value and should be highly recommended. These exercises should be practised twice daily and should not be carried to the extent of tiring the patient. Operative interference may be indicated, especially in cases in which the condition results from infantile paralysis and congenital deformities.

Wiener klinische Wochenschrift.

February 3, 1921, xxxiv, 5.

Operations on the Tonsils During Sepsis.—Rethi does not refer necessarily to acute septicemia but chiefly to the low grades seen when purulent foci in the body have led to a bacteriemia and the tonsil is thought to be a focus. Such operations when performed on singers are apparently followed at times by impairment of the singing voice. The author formerly made many tonsillectomies, but the detention from business and like drawbacks have made him more conservative. There are operative risks and postoperative complications and in addition the injury to the professional voice—the latter sequela not being due to any operative insuccess. Since 1910 he has learned that splitting the tonsils is sufficient in cases of suspected septic focus and that various partial operations, generally speaking, answer as well as enucleation in many cases. In regard to sepsis many tonsillar interventions are of course solely prophylactic, to avert, say, a possible nephritis. Under sepsis the author includes the acute fulminating cases as in one example, doubtless of the cryptogenic kind, with septic pneumonia and nephritis, in which the disease picture subsided after the operation of splitting the tonsil. After this experience the author performed the same operation in cases of milder sepsis, avoiding tonsillectomy, particularly in singers. The author cites cases by American laryngologists in which depreciation of the voice in singers was associated with operative sequelae, including scar formation, but his personal cases occurred in part among those persons upon whom a perfect operation had been performed.

December 11, 1920, III, 2.

Results of Operations for Cancer of the Breast During the Years 1898-1915.—Brattstrom of Professor Borelius's Surgical Clinic, Lund, gives some statistics of 138 cases of cancer of the breast treated by extirpation from 1898 to 1908. There was one operative death—the patient had decompensation of the heart and was operated on without narcosis. Of the 137 cases 50 are known to have had recurrences, while in 54 the operations were of too recent date for three-year interval statistics. Six patients had disappeared from observation. This leaves but 27 cases of nonrecurrence in a total of 77 cases—a percentage of 35. These figures were of course compiled long ago. Another series was made up of operations performed from 1905 to 1915. This material evidently overlaps the first and should not be added on. There were 212 cases with one operative death—from pulmonary embolism. Of the 211, 90 patients are already dead of recurrence while 45 live with recurrence, making a total of 135. Thirteen others are lost track of. Survivals of 3 or more years alive and recurrence free number 63. The percentage of recovery is but 31.8. While 19 patients have survived over 9 years, there have been equally late recurrences—one at 7 and one at 9 years. The author has made some attempts to tabulate and analyze the total material from 1898 to 1915, but his figures are incomplete. The total operated on is nearly 300 (297). The operative mortality of 2 cases in nearly 300 is less than 1 per cent. (0.67 per cent.), and apparently he has broken all accessible records. Total untraced is 39. Total recurrences, living and dead, 181. Three year sound survivors 29.2 per cent., which appears to lead the record in Europe; 5 year survivors 23 per cent.; 9-10 years 12.1 per cent. Of the 75 three year survivors 22 had metastases in the axilla at the time of operation. Of the 39 who disappeared many doubtless survive.

Acta Chirurgica Scandinavica.

January 20, 1921, III, 3.

Cultivation of Nerve Tissue.—Henriksen's article on this subject appears in English text. While the cultural aspect is given in full the conclusions of the author bear principally on the subject of regeneration of severed nerves. If a nerve is severed the nourishment supply and the innervation remain intact in the central stump. A profuse growth of protoplasma threads appears after 4-5 days, and fully differentiated medullated nerve fibers after 10 days. In the peripheral section both supply and innervation must be reorganized. The development of protoplasma goes on slowly, and a few fully organized medullated nerve fibers appear after 3-4 weeks. If the accretion of the nerve is prevented the nutrition is established but not the innervation. Formation of medullated substance does not appear till after two or three months, and development does not become complete. If the nerve cell is taken out of the organism and planted in the plasma no growth appears. If the regeneration is allowed to start within the organism, the growth will continue some time after transplantation into plasma. It has not yet been shown whether or not a certain amount of differentiation is possible.

Epiphyseolysis of the Head of the Femur.—Abrahamson shows by x-rays that this affection may occur after minimal contusions and abrupt movements. One accident may detach the cap of the head of the femur and a second one displace it. The symptoms may be quite slight—a mere limp perhaps—and pain may be absent. The author believes that coxa vera is always traumatic although the accident may be slight enough. A radiogram is imperative after any suspicious injury. The separation must be reduced and a Lorenz-Löfberg bandage applied—even after the lapse of much time this must be the management.

Gazette des Hôpitaux.

February 12, 1921, xciv, 13.

Wounds of the Ureter.—Oeconomus of Athens writes systematically of this subject. Rupture is not included.

Operative wounds is a subject which goes back chiefly to 1890. In 1902 there were at least 62 cases on record and in 1914 this number had been increased to 159—this despite the improvements in operative technique. The number of special articles, theses, etc., on this subject is large. The author enumerates ten which appeared before 1890 and naturally many have appeared since. Accidental wounds of the ureter were very rare before the late great war. The author now devotes much space to the anatomy and surgical anatomy of the canal in the two sexes. He then reaches the subject of etiology and as far as France is concerned finds but 15 cases in literature, including military ones, although manifestly this figure is absurdly low. There were but two cases in the world's literature before 1914, one being a fatal case in the Archbishop of Paris in 1848, who was killed by a projectile. There are no stab wounds on record, although a boy of nine was once killed by falling on a spiked fence. But few obstetrical cases are on record, although many operative cases have resulted from intravaginal operations. In connection with laparotomy there have been numerous voluntary resections of the ureter. In 735 cases of Wertheim operation performed by the latter for cancer there were 11 such cases. Involuntary wounds have been due to no one causal factor. In some cases the course of the canal was anomalous or there was a congenital abnormality. In others the "three rules of Latzko" were violated in some particular.

Norsk Magazin for Laegevidenskaben.

February, 1921, LXXXII, 2.

Treatment of Poliomyelitis.—Saethre gives a description of the treatment of this affection as it has been developed in the Neurological Division of the Rikshospital. He emphasizes the importance of early treatment—at the very onset of the disease. During the earlier stages the indications are to prevent deformities and the overstretching of muscles. When all pains and hyperesthesias have disappeared and Kernig's sign has become negative the treatment may be said to be in its second stage. Here it is of the utmost importance to avoid overstretching the muscles and ligaments. The chief indication, however, is the development and utilization of voluntary innervation of the different muscles aided by electrical treatment and massage. To avoid dangerous overstretching the author gives some simple home resources which can be improvised in every house. Saethre is inclined to think that faulty or defective treatment is responsible for almost as much functional loss after poliomyelitis as is the actual destruction of the anterior horn cells.

The Centripetal Part of the Reflex Arc in Abdominal Reflexes.—Monrad-Krohn and Saethre refer to the monograph of the former (1918) in which it was maintained that the centripetal part of the arc corresponds to the uncrossed fibers of the posterior columns, as deduced from a study of the Brown-Sequard syndrome. But one case was studied up to that time, but in the present article three others are given. All four showed that these fibers have no connection with those conducting impressions of pain and temperature. In all, the reflexes were present on the side presenting hemi-hypalgnesia and hemi-hypothermesthesia and were absent on the opposite side. Their absence on the side of motor loss proves nothing, for the latter may be due to lesion of the pyramidal tracts. But presence on the side of sensory loss suggests that the sensory properties have no connection with the reflex arc.

The Bubonic Plague in Infants.—The recent episode of plague in Paris showed a strong tendency to attack children, and it is important to know the clinical picture of the disease in tender years. The appearance of purpura, a variolous eruption, and suppurating nodules is significant, and here a bacteriological examination of discharges should include a research for the *B. pestis*. Angina is practically always present at the outset. A slight meningeal reaction is common, but only rarely has this been so pronounced as to suggest epidemic meningitis. The early meningeal phenomena show clear spinal puncture fluid without the *B. pestis*, and only in the secondary meningitis do we find pus and bacteria in the punctate.—*La Presse Médicale*.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

OHIO STATE BOARD OF MEDICAL EXAMINERS.

Columbus, December 1-3, 1920.

(Continued from page 725.)

PRACTICE.

1. Mention some of the causes of acute cystitis. Give symptoms and treatment.
2. Give etiology, symptoms, diagnosis and treatment of arteriosclerosis.
3. Give symptoms, diagnosis, and treatment of acute pleurisy.
4. Give symptoms and diagnosis of typhoid fever in its early stage.
5. Give the symptoms, diagnosis, and treatment of diphtheria, with a brief statement as to the dangers of the use of antitoxin and how they may be avoided.
6. Give the symptoms and treatment of tetanus. In what class of injuries would you advise the prophylactic use of antitetanic serum?
7. Give the etiology, symptoms, and treatment of bronchial asthma.
8. Give the symptoms of angina pectoris and treatment (a) during attack (b) between attacks.
9. What symptom complex is meant by *apoplexy*? What three pathological conditions may account for it, and how differentiate them?
10. Give the symptoms, and treatment of wood alcohol poisoning.

ANSWERS.

PRACTICE.

1. ACUTE CYSTITIS. *Causes:* (1) gonorrhea spreading to the bladder; (2) the presence of foreign bodies or after operations; (3) the introduction of sepsis on instruments or mucus, as in paralysis of the bladder from spinal injuries. Cantharides and cold in gouty subjects are said to produce cystitis.

Symptoms.—(1) Pain and tenderness over the hypogastrium; (2) frequent and painful micturition, only small amounts being passed (strangury); (3) pyuria. The temperature is raised, and there is tenesmus. The case usually terminates by resolution, though irritability of the bladder may remain. Sepsis may spread to the kidney, and cause fatal toxemia. In some cases retention, distension, and atony occur if the neck of the bladder is chiefly affected. The wall of the bladder may slough in very severe cases.

Treatment.—The patient must be kept in bed with hot fomentations over the hypogastrium. A fluid diet, with plenty of barley-water, must be given. Alkalies and hyoscynamus, with morphine suppositories, relieve the pain. Urotropin (gr. x. t.d.s.) is the best internal antiseptic. If the urine is very foul, the bladder may be washed out. In sloughing cystitis median perineal drainage is necessary, but these cases are usually fatal. (*Aids to Surgery*).

2. ARTERIOSCLEROSIS. *Causes.*—"The principal etiological factors are senility, heredity, male sex, alcoholism, syphilis, lead-poisoning, diabetes, malaria, gout, rheumatism, lithemia, Bright's disease, exposure, and excesses of various kinds. The condition of the arterio-capillary system may be taken as an index of an individual's age. The main factors are time, tension, and toxins."

Symptoms.—These are not always apparent and vary with the arteries involved and their distribution. When the process is general, the peripheral arteries have a hard bony feel, not unlike whip-cord. The increased resistance of the arterial system induces increased cardiac activity and consequent hypertrophy. Attacks of vertigo, pseudo-apoplectic attacks, or spells of unconsciousness in the aged or those having superficial hardened arteries, are generally due to changes in the cerebral vessels. Evidences of myocarditis and angina pectoris point to atheroma of the aorta and coronary arteries. Renal arteriosclerosis manifests itself as chronic interstitial nephritis. Gangrene of the extremities in the old—senile gangrene—point to atheroma or thrombi, the result of the fibrosis.

Treatment.—"The habits, hygiene, mode of life, diet, etc., should be most carefully regulated. When the cause or causes are detected they should be promptly removed. The secretions should be kept free at all times. Constipation should be avoided, as it serves to embarrass the functional activity of the liver and kidneys. Alcohol should be interdicted. Moderate exercise is of benefit. Potassium iodide and nitroglycerin should be administered in small doses indefinitely. Over-exertion of any kind should be avoided." (*Hughes' Practice of Medicine*.)

The diagnosis is made from the symptoms, mainly the thickened arteries, and in addition the hypertrophied condition of the left ventricle and the high blood pressure.

3. ACUTE PLEURISY. *Symptoms:* "Pleurisy is ushered in by—(1) slight or repeated chills; rigor is uncommon; (2) rapid ascent of temperature (which is not so high as in pneumonia); (3) lancinating, tearing pain in the side, rendered worse by any respiratory act; the pain may be referred to the epigastric or umbilical region. As the disease advances, and effusion takes place, the severe pain becomes replaced by dyspnea. The patient lies on the affected side to give the sound lung more freedom. The respirations are hurried, the pulse quickened, and the cough is hacking in character; the sputum is, however, slight in amount, mucoid in character, and never rusty, unless pneumonia exists as a complication.

Diagnosis. "The examination of the cellular contents of the fluid may help to determine the character of the pleurisy. In tuberculous pleuritis these cells are largely lymphocytes, while polymorphonuclear cells prevail in simple inflammations." (*Wheeler and Jack's Handbook of Medicine*.)

PLEURISY WITH EFFUSION.

Onset marked by chilliness persisting for a few days.

Cough is irritating; or, if expectoration, or, if present, catarrhal in character.

Sputum negative; tubercle bacilli rare.

Moderate fever of continuous type; declines by lysis.

Prostration moderate. Unilateral distention of the thorax.

Countenance pale and anxious.

Limited expansion at base of chest on the affected side.

Tactile fremitus diminished or absent.

Interspaces bulging at base of chest.

Percussion shows flatness, with great resistance to the pleximeter finger.

Diminished or absent breath-sounds over effusion the rule. Respiration murmur diffuse, distant, and generally unaccompanied by rales.

Bronchial breathing may be present over the entire affected side of the chest.

Friction sound heard in early and late stages.

LOBAR PNEUMONIA.

Onset acute, with rigor, lasting one hour or longer.

Cough more marked, and accompanied by rusty or bloody, tenacious expectoration.

Dense aggregations of pneumococci present.

Fever, 102° to 104° F.; falls by crisis.

Prostration extreme. Absent.

Mahogany-colored flush of cheeks.

Degree of expansion slightly, if at all, inhibited.

Increased over area of consolidation.

Absent.

Dullness with less resistance, and sometimes a tympanic note.

Harsh bronchial breathing and presence of rales in first and third stages, unless a bronchus is plugged.

No friction murmur; rales present.

(Anders and Boston's Medical Diagnosis.)

Treatment: "In dry pleurisy relieve pain by a blister or if need be by morphine. In pleurisy with effusion, fever diet and a free purge are necessary at the outset. Pain may be relieved by morphine or Dover's powder, leeches, or strapping the affected side to restrict its movements. If the exudate is only

moderate in amount, an attempt may be made to promote absorption by the daily administration of a concentrated solution of magnesium sulphate, of which 5iv to 5vi may be given before breakfast in $\frac{3}{4}$ of hot water. The free purgation induced may, however, prove exhausting to weakly patients. Externally, liniment of iodine is often used, but inunction of mercurial ointment is more effectual. During convalescence, nourishing diet and tonics, such as arsenic or the hypophosphites, should be employed, and respiratory exercises should be begun early to aid expansion of the lung. If the fluid is not rapidly absorbed (within two or at most three weeks), it should be removed by aspiration, which may be repeated on re-accumulation. Aspirate at once if there are signs of serious pressure on the heart or interference with breathing, and always if the dullness reaches the level of the second rib in front." (Wheeler and Jack's *Handbook of Medicine*.)

4. EARLY STAGE OF TYPHOID FEVER. *Symptoms:* Insidious onset, weakness, headache, epistaxis, vague pains. The temperature rises gradually, about 2° in the evening, falling 1° in the morning. Diarrhea, tenderness in the right iliac fossa, enlarged spleen, and a characteristic rash which appears from seventh to twelfth day. During the second week the temperature remains at a uniform level; typhoid state and delirium may be present. The pulse becomes rapid, weak, and dicrotic; the heart sounds are feeble; the tongue is coated, fissured, and tremulous; sordes appear on the teeth; the abdomen is distended; the stools are yellowish and offensive (said to be like pea soup); the Widal reaction may be positive.

The diagnosis may be made from the symptoms, the rash, enlarged spleen, and characteristic temperature chart. In the first few days the typhoid bacilli may be isolated from blood cultures; but in the early stage can not be obtained from the stools or urine. The Widal reaction may be obtained in the second week.

5. DIPHTHERIA. *Symptoms:* Slight fever, malaise, pain in neck, redness of soft palate and fauces with whitish patches which may coalesce and form a membrane, which at first may be removed, but it reforms, and is then adherent; the neighboring glands may enlarge. The temperature rises to about 100° or 102° F.

Diagnosis is made by finding the diphtheria bacilli in the exudate. A sterile swab is rubbed over any visible membrane on the tonsils or throat and is then immediately passed over the surface of the serum in a culture tube. The tube of culture, thus inoculated, is placed in an incubator at 37° C. for about twelve hours: when it is ready for examination. A sterile platinum wire is inserted into the culture tube, and a number of colonies of a whitish color are removed by it and placed on a clean cover slip and smeared over its surface. The smear is allowed to dry, is passed two or three times through a flame to fix the bacteria, and is then covered for about five or six minutes with a Loeffler's methylene-blue solution. The cover slip is then rinsed in clean water, dried, and mounted. The bacilli of diphtheria appear as short thick rods with rounded ends; irregular forms are characteristic of this bacillus, and the staining will appear pronounced in some parts of the bacilli and deficient in other parts.

Treatment includes isolation, rest in bed, liquid diet, washing of the throat and nose with an antiseptic solution, and injection of the antitoxic serum. About 5,000 units may be given at once, and another dose of half this amount in from twelve to twenty-four hours if necessary. The antitoxin should be given (in as large a dose as is necessary) within twenty-four hours, and not spread over several days. By observing this rule, anaphylaxis may be avoided. Hypersensitiveness or anaphylaxis is the main danger in giving antitoxin. The subcutaneous method of injection is the safest.

6. TETANUS. *Symptoms:* Acute Tetanus usually begins five to fifteen days after infection, preceded for a day or two by malaise and neuralgic pain about the wound. The muscles of mastication are first affected. They are contracted firmly, and there is a cramp-like pain in them (*trismus*). The muscles of the neck and face are next affected (*risus sardonius*). Dysphagia is due to contraction of the pharyngeal muscles. Contraction of the trunk muscles follows, called *opistho-*

tonos if the body is arched backwards; if doubled forwards it is called *emprosthotonos*; if to one side, *pleurosthotonos*. Contraction of the limb muscles follows. The muscles of respiration are, fortunately, the last to be attacked. The characteristic feature is that the spasm is never entirely relaxed, yet the least stimulus, such as a noise or a draught of air, induces violent tonic contractions, which may be so severe as to rupture the muscles. The pulse is rapid, the temperature is generally raised, sweating occurs after the convulsions, and the patient is unable to swallow. Consciousness is unimpaired till the end, which is generally due to exhaustion from the poisoning and the continuance of the convulsions, rarely to asphyxia from prolonged fixation of the respiratory muscles. Death occurs in one to four days.

Treatment:—"Prevention by careful antiseptic treatment of all wounds. The infecting wound should be freely excised and purified. Amputation is unnecessary, unless it be a finger or a very septic compound fracture of a limb. Antitetanic serum, which is the serum of an immunized horse, should be injected in doses of 20 c.c. every twelve to twenty-four hours till symptoms cease. Unfortunately, the serum only prevents the further development of the organisms, but is unable to combat the tetano-toxin already absorbed. General measures consist in keeping the patient in a quiet darkened room. Fluids should be given by the nasal tube if trismus is marked. Chloral should be given in doses of 20 grains every two or four hours, and chloroform administered during the severe convulsions. Chloral and chloroform are only palliative remedies; there are no drugs yet known which can cure tetanus." (*Aids to Surgery*.)

The prophylactic use of antitetanic serum is indicated in cases of punctured wounds, particularly those contaminated with soil, or made by rusty nails or dirty wood; also in gunpowder wounds, wounds made by fire-crackers, pistols, or in "Fourth of July" rejoicings.

7. BRONCHIAL ASTHMA. *Etiology:*—"The disease sometimes occurs in children, and when it does so there is usually a history of naso-pharyngeal trouble, measles, whooping-cough, or imperfect recovery after capillary bronchitis. More frequently it is a disease of adult life, in which heredity is an important factor. There may be a family tendency to gout or phthisis, or to nervous complaints, and probably most cases have a neurotic origin. Asthma is much more frequent in males than in females, possibly because of their greater liability to bronchial affections generally. An attack may be induced by a variety of circumstances—change from country to town, or from town to country, an overloaded stomach, certain odors, fright or emotion. The exciting causes are either direct irritation of the bronchial mucosa, or indirect irritation through the nervous system or the blood.

Symptoms:—" (1) *Premonitory Symptoms.*—There is usually some visceral disturbance, such as flatulence, etc., but the onset may be quite sudden. (2) *The attack* occurs most frequently during the night, the patient waking up with a feeling of great dyspnea; he feels as if there were not sufficient air in the room, and asks for the windows and doors to be opened. The characteristic attitude of asthma is assumed—i.e., the patient grasps some support to fix the shoulder girdle, in order to bring his extraordinary muscles of respiration into play. Expiration is much prolonged, and accompanied by sibilant rhonchi, which causes a peculiar, noisy piping or wheezing. Respiration is not accelerated, though in spite of the extraordinary efforts little air enters the lung. A paroxysm of coughing and expectoration gives relief, or even terminates the intense dyspnea and sleep may supervene, or a slight lull may be succeeded by another paroxysm. The sputum is usually expelled with the greatest difficulty, and is distinctly peculiar in its composition. It consists of ball-like gelatinous masses, which can be unfolded, and are then found to represent casts of the small bronchioles."

Treatment:—" (1) *During the Attack.*—Remove any obvious cause of reflex irritation, such as overloading of the stomach. A brisk emetic often cuts an attack short; nitrites, especially nitrite of amyl, or chloroform may be inhaled. Belladonna, stramonium, and lobelia in combination with ammonia are useful remedies; the fumes of burnt niter papers, etc., are also recommended.

A hypodermic injection of morphine may be needed; and pilocarpin or adrenalin may also be used hypodermically. The drug which has most claim to be regarded as specific is iodide of potassium. It should be given during the intervals and steadily persevered with. It is often successful, but as often fails, the disease being very refractory to treatment. (2) *During the Intervals*.—Change of air, careful diet, cod-liver oil, tonics, etc. A suitable climate must be found by experiment in each case. Such sources of reflex irritation as nasal disorders, gastro-intestinal irritation, uterine or urethral disease, must be sought for and removed. The diet must be light and non-stimulating, and the general health must be kept at the highest possible level." (Wheeler and Jack's *Handbook of Medicine*).

8. **ANGINA PECTORIS.** *Symptoms*.—"The chief symptom is intense agonizing pain which begins in the region or the heart and extends to the neck and down the left arm. Shortness of breath, and precordial oppression are present. The chest is fixed and the heart's action is weak and feeble. The face is pale or ashen gray, the expression is anxious, and there is a fearful sense of impending death. The body and face are covered with drops of cold sweat. The pain usually lasts but a few seconds or minutes. Extreme prostration follows the attack unless it is terminated meanwhile by death. The end of the paroxysm is marked by cessation of the pain and precordial distress, and by vomiting, or excessive flow of urine. The first attack may end in death or there may be a recurrence at varying periods, sometimes extending over years."

Treatment.—"The Attack: Prompt relief follows the immediate inhalation of amyl nitrite, m^{ss} to v , or chloroform, or the hypodermic injection of morphine sulphate, gr. $\frac{1}{4}$, combined with atropine sulphate, gr. 1/100, or nitroglycerin, gr. 1/100 to 1/50. In many cases, the use of nitroglycerin, gr. 1/100, three times daily, over an extended period, lessens not only the frequency but also the severity of the paroxysm. Chlorodyne, m^{ss} to xv , repeated often affords relief. Sparteine sulphate, gr. $\frac{1}{4}$, three times daily is also highly recommended. The application of a mustard plaster or other form of counterirritation to the precordium is productive of considerable benefit.

The Interval. Attempts should be made to remove the exciting causes or to diminish their influence. Great care should be exercised in the diet that flatulency and constipation do not occur. Mental excitement and physical exertion should be avoided. When structural changes are suspected; potassium iodide, gr. x to xx , three times daily, should be administered. The nitrites, and nitroglycerin should be employed as they lessen materially the frequency and severity of the paroxysms. Tonics such as iron, arsenic, strychnine, phosphorus, etc., are of value in that they increase the resistance of the body and improve its general tone. Strophanthus and strychnine are indicated when the heart is weak." (Hughes' *Practice of Medicine*).

9. The symptom complex in *apoplexy*, is:—Sudden unconsciousness, coma, muscular relaxation and paralysis. The pathological conditions which may account for it, are cerebral hemorrhage, thrombosis and embolism.

Caille gives the following differential diagnosis: "*Cerebral Hemorrhage* occurs after the age of fifty-five, as a rule, with atheromatous arteries and an hypertrophied heart. The onset is sudden, with coma, during exertion or excitement. The temperature falls in an hour, and then rises, sometimes to 106° F. Gradual recovery of consciousness takes place in from three to five days, with permanent hemiplegia.

"*Cerebral embolism* comes at any age, with heart disease or after childbirth. There is a sudden onset, without loss of consciousness or with slight mental confusion, or with rapid return to consciousness. The temperature does not fall, but may rise as high as 102° F. Improvement occurs within twenty-four hours to a marked degree, but after three or four days the symptoms return. Monoplegia, hemiplegia, or aphasia may remain. Jacksonian epilepsy may develop if the lesion is cortical, involving a special center.

"*Cerebral thrombosis* occurs at any age, but chiefly in syphilitic persons and middle-aged men. There are usually premonitions. The onset is slower, without coma, but with dullness of the mind. The temperature

does not fall, but may rise to 100° F. The paralysis is similar to that observed in embolism. The diagnosis between these three conditions is hardly ever positive."

10. **Poisoning by wood alcohol.** *Symptoms*.—"The acute symptoms resemble ordinary alcoholic intoxication. The main differences are in the stronger irritation and in the more protracted and more serious after-effects, the coma lasting several days and often terminating in death. A very important feature is the frequent occurrence of incurable blindness from retrobulbar neuritis and retinitis. . . . The general symptoms begin with gastro-intestinal disturbance, abdominal pain, general weakness, nausea, vomiting, vertigo, headache. The symptoms of ordinary alcoholic intoxication supervene, with delirium, restlessness, unconsciousness, collapse, and coma. The pupils are usually dilated and irresponsive; nystagmus may be present. Dyspnea and cyanosis are marked. The temperature is subnormal. Death is very much more frequent than with ethyl alcohol. It occurs in coma, from respiratory paralysis, in a few hours to three days. Sometimes the symptoms are deferred for several days and then prove rapidly fatal. Delirium may set in after the acute symptoms have subsided. Cystitis is a frequent sequel. The most important sequel, however, is the optic injury. The symptoms are bilateral and consist in scotoma, dimness or total blindness; the pupils are dilated and insensible to light. The loss of vision may start in a few hours, or be delayed several days; it generally becomes complete; subsequently there is some improvement, which in most cases, however, finally relapses into total blindness."

"The treatment of poisoning by wood alcohol includes evacuation, stimulants, heat; and morphine to allay suffering." (Sollmann's *Manual of Pharmacology*.)

(To be continued.)

Society Reports.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

One Hundred and fifteenth Annual Meeting,
Held in Brooklyn, N. Y., May 2, 3, 4 and 5, 1921.

HOUSE OF DELEGATES.

First Day—Monday, May 2.

THE SPEAKER OF THE HOUSE, DR. E. ELIOT HARRIS OF NEW YORK, IN THE CHAIR.

Address of the President.—Dr. J. RICHARD KEVIN of Brooklyn submitted this address in the form of a report. He said, in part, that it was obvious that in this period of reconstruction in our institutions that Practice of Medicine was not escaping the vision of the so-called reformers. At no time in the past history of the State Society had the need for a more militant body presented itself. The shadow of portentous events was upon us. The profession, to be recognized, must speak with one voice. When we considered the fact that each year we had to meet the Antivivisection, the Chiropractic and the various other Cult bills, it necessarily meant that we should wake from our apathy. Various County Societies, no longer depending on the State Society for its function, so far as the economics of the profession was concerned, had organized independent guilds to combat the menacing legislation appearing at Albany each year. This brought about a desultory method of approaching a solution which, to be successful, must, in the final analysis, reside in the parent body. Because of lack of funds the Society had not properly functioned from the economic standpoint. The dues which had been in vogue were adequate for the sustenance of the Society years ago; but to meet the present conditions and new environments, necessarily meant a radical increase. Because of these reasons, Dr. Kevin said he recommended the amendment to the By-laws which made the dues five dollars a year. He also recommended that provisions be made whereby the office of Executive Secretary be promptly established. When one studied the support given by the public to the various cults and mediums that sprung before the

Legislature each year it caused one to pause and reflect; one wondered how they obtained such surprising support. He was of the opinion that a large factor in the product of their success lay in the inertia of the medical profession. While the profession held itself aloof, these groups took the public into their confidence; by their cunning methods they were apparently successful in obtaining many new recruits to their cause each year. In the Constitution defining the purposes of the Society Article 1 read, "to enlighten and direct public opinion in regard to the great problems of State Medicine." With this end in view the Committee on Arrangements had planned that on Sunday, May 1, about one hundred of the clergy in Brooklyn would vacate their pulpits, and in these vacant pulpits physicians and surgeons would discuss preventive medicine and the problems of health. Dr. Kevin recommended that an expression of approval and encouragement by the House of Delegates be recorded; to the end that all future meetings of this Society, when possible, would include a similar program.

Dr. Kevin stated that he had visited all the District Branches of the State Society during his term of office, that they were generously attended, and the enthusiasm exhibited suggested their great usefulness as branches of the parent body. The scientific programs were of the highest character, the discussions liberally contributed and the economic questions of medicine prominently discussed.

Address of the Speaker.—Dr. E. ELIOT HARRIS of New York presented this address in which he considered the Constitution and By-laws of the Medical Society of the State of New York, and especially those provisions which would be helpful in the work of carefully and expeditiously carrying out their duties as members of the House of Delegates. He quoted one provision of the Constitution which made it the business of the delegates to keep informed as to the work of the graduate, the post-graduate, and the research institutions of the State; and to aid in protecting them from selfish propaganda and misguided legislation that would lower the standards of medical education and licensure, and hamper medical research. The further purposes suggested that the activities of the State and local Departments of Health, the molding of public opinion in harmony with the medical profession, the medical needs of the smaller and larger communities of the State, and the protection of the people from being exploited by quacks, charlatans and pretenders of all sorts, were problems which should be carefully studied by the delegates, and finally a policy should be adopted which could be carried out by the executive body, the Council. After reviewing the duties of and functions of the House of Delegates, the Council, standing committees, etc., Dr. Harris said he could not refrain from taking this opportunity to express to the House of Delegates his appreciation of the honor conferred upon him in electing him the first Speaker of the House. He said he was aware of the obligation he assumed in accepting the office and it was his earnest wish to serve this House as its presiding officer, in a way that would call out the sympathetic cooperation of the members. He said the House of Delegates represented and acted for the Medical Profession of the State of New York, because more than a good working majority of the profession were members of the Medical Society of the State of New York and *ipso facto* of the counties that had elected them delegates. It was sound American doctrine that the majority should rule. Let them rule wisely and well. It was expected of the carefully selected delegates of the medical profession in annual convention assembled to give to the profession of the State something eminently worth while as a result of their deliberations. Never before in the medical history of this State had there been more vital problems affecting medical economies such as the relation of physicians and of the practice of medicine to the community, than those which were demanding their immediate thought and action. Might their minds trained in scientific accuracy search out and marshal the facts which were needed to produce concerted action on the part of the profession, and which would help to secure that kind of public support which was best expressed in right legislation.

Report of the Secretary.—Dr. EDWARD LIVINGSTON HUNT of New York submitted this report, which showed that the Society had lost 125 members by death and 88 by resignation during the year, leaving a total of 8,671 members, just 100 more than on January 1, 1920. The honor list of counties which showed both dues and taxes paid was as follows: Columbia, Essex, Greene, Ontario, Oswego, Richmond, Schoharie, Warren, Washington and Yates. This report recommended the amendment of the Constitution, introduced at the last annual meeting raising the per capita assessment from \$3 to \$5. He also recommended that the House of Delegates levy a special per capita tax for the year 1921 similar to the one levied in 1920, since the increase in dues could not become effective until 1922. Dr. Hunt called attention to the proposed amendment to the Constitution in regard to the apportionment of the delegates from the County Societies. He recommended the adoption of this amendment. He asserted that the reorganization of the Legal Department was the most important and urgent matter which would come before the House of Delegates. The Society should have the best legal talent and should be prepared to pay for it. No new financial obligations should be incurred until a sufficient sum should have been appropriated to maintain a first class legal department. The Society should have such a department; and to insure its efficient functioning, it should be directly under the control and supervision of a special legal committee. He, therefore, recommended that a committee be appointed to consider the establishment of such a legal department, and that this committee suggest an appropriation requisite for the maintenance of the Department. The Committee of Legislation had assumed a position of great importance in the Society. It had in the past year accomplished much and if given proper recognition and aid could be invaluable to the society. It should be given more power and wider scope. It needed clerical help and an appropriation. He therefore recommended that ways be considered to strengthen and assist this committee and that an appropriation be made to provide a permanent clerk during the sessions of the Legislature. It was desirable to have an Executive Secretary; there were two essentials necessary to the appointment—big man and a big salary. The *Journal* has been much improved and strengthened. If the finances of the Society warranted the outlay it would be advisable to enlarge the *Journal*. An important step taken by the Council during the year was the creation of an Executive Committee, for the more efficient administration of the affairs of the Society. This committee met monthly, had supervision over the finances and publications of the Society, and acted as advisers to the legal counsel. It in no way interfered with the meetings of the Council.

Report of the Treasurer.—Dr. HARLOW BROOKS of New York submitted this report, which showed an excess of income over expenditures for the year 1920 of \$4,499.96. The expenses for the year were \$33,510.13.

Report of the Council.—The Council, through its secretary, Dr. E. L. Hunt, submitted this report, which consisted of a record of the meetings held during the year, and a set of resolutions, providing that all standing and special committees of the society should be under the direction and subject to the orders of the Council while the House of Delegates should not be in session, and that the Council be charged with carrying out the Constitution, By-Laws, and rules, regulations, and orders of the House of Delegates.

Report of Committee on Arrangement.—Dr. WILLIAM FRANCIS CAMPBELL of Brooklyn reported for this committee. He called attention to two features of the program, which were innovations, and were presented solely for their educational value to the community in which the convention was held. They believed that their annual conventions should be altruistic and not egoistic. The annual convention afforded a unique opportunity to awaken and interest the local community in matters of public health, sanitation and hygiene. The convention of the State Medical Society should be an annual event not merely for the profession, but sought and welcomed by progressive communities for the educational advantages which it con-

ferred, and the stimulus for higher civic ideals which it bequeathed to its host. To crystallize these ideas this committee had inaugurated two important features. It had planned to make convention week contemporaneous with "health week" for the Borough of Brooklyn, inaugurated by fifty "health talks" on Sunday, and it had planned an unusual scientific exhibit which would be in the fullest sense a health exhibit. While it retained all the features which made a personal appeal to the physician, it had extended its activities to include every department of health and hygiene. These innovations were placed on trial.

Report of the Committee on Medical Economics.—Dr. HENRY LYLE WINTER, of Cornwall, submitted this report, which stated that the work of the committee had touched upon most of those phases of our present day complex social life which affected the medical profession. As a result of their studies they were able to assure the Society that the science and art of medicine were making equal progress with other activities of civilization. They had been importuned, and had importuned others, to join in constructive criticism of such schemes as health insurance and health centers. They had studied these plans and the conditions which they were assumed to help, or which they assumed to exist, actuated only by the desire to get out of them or put into them, those things which were for the good of the public and the medical profession. The result had been an *impasse*. They found that these plans did not permit of constructive criticism because they fundamentally obstructed the normal development of medicine. This being the case the medical profession could find no justification in any other attitude than unequivocal opposition. Aside from other vicious effects, the pessimism regarding the value of medical services and the future of medicine which their legislative efforts tended to produce had a disastrous effect upon the public by indirectly aiding the propaganda of quackery. No one criticized the quack, and he fattened upon the discredit cast upon the efforts of the medical profession. Taking up the matter of health centers, the report shows that rural communities are not as badly off for medical service as reports would lead one to believe, and that there was no cause for anxiety that a sufficient number of physicians would not be available in the future, or that service would not be of the best. Considering the Health Center bill specifically, the committee could find no excuse for its passage. It was vicious in its purpose, tending to centralize certain powers in the State Department of Health, which could only develop to their fullest fruition as functions of the individual physician acting alone or as a member of a group. They believed that it was wise that laboratories should be standardized, but they did not consider that the actual work of the laboratories or the activities of physicians who specialized in laboratory work should be in any way controlled by the State Department of Health. They believed that the State should assist in establishing laboratories in sections of the State where they might be needed, but they also believed that such financial aid should be discontinued as soon as the laboratories became sufficiently self-supporting. What was true of laboratories was true of other phases of medical practice. This report recommended that the State Department of Narcotic Drug Control be abolished; endorsed the Medical Practice Act as amended and introduced at this session of the Legislature, and recommended continued opposition to health insurance. During the year the committee had communicated with all of the county societies with reference to the Health Center bill. The replies received from most of the societies showed strong opposition to the bill.

Report of Committee on Public Health and Medical Education.—Dr. JOSHUA M. VAN COTT of Brooklyn submitted this report, which stated that the committee had watched with interest the various bills pending in the Legislature during the year just past calculated to affect public health and medical education. Fortunately, they all either died in committee, had been vetoed by the Governor or had failed to become laws. In the last analysis every physician in the State should regard himself as a public health officer, whose efficiency of work in his own community must depend

largely upon his ability, probity and personal unselfishness. The difficulty at present seemed to lie, not so much in lack of desire on the part of medical men to do their share of public duty, as in lack of proper directive. The action of the Council in creating an Executive Committee from its own number to meet frequently with power to transact business for the Council would go far toward overcoming the difficulties encountered in meeting sudden emergencies in the Legislature involving important questions of public health and medical education, in increasing the efficiency of the standing committees, and in dealing with those problems more directly related to the individual physician. They felt that more than ever before every physician in the State should consider it his duty to keep informed of all matter pertaining to public health and hold himself ready for any personal service that he might be asked to perform in this relation. He must be willing to spend the time and energy necessary to inform influential people in his community of the menace to the public of efforts at vicious legislation which, if successful, would be disastrous. When asked to write to his Assemblyman, Senator, or Governor, he must waste no time in doing it. Indeed, if asked to attend the hearings in Albany on questions of vital importance to public health and medical advancement he must unselfishly go. This committee recommended that the direction and control of standing committees be placed under the Council of the Society; otherwise they must remain as little more than dead letters. It further recommended the disapproval of the Curtis-Rainey bill, as reported by the Ways and Means Committee of the House at the last session of Congress, for the following reasons: (1) The limitation of the importation of narcotics in the raw materials would endanger a shortage of these drugs at a time when it might be calamitous. Not even the medical profession could always foretell the advent of epidemics or other circumstances which would imperatively call for their use in larger quantities than could be rightfully required under normal conditions. (2) On the other hand, the limitation of importation of the raw materials would, *ipso facto*, create the danger of monopoly by manufacturers, who could obviously control both price and quality of the refined drugs.

Report of Committee on Medical Research.—Dr. FREDERIC E. SONDERN of New York submitted this report which stated that during the current session of the Legislature bills were introduced intended to restrict research, by excluding dogs for purposes of investigation or experiment. Public-spirited individuals, and members of this committee, had actively protested to the members of both branches of the Legislature in person and by letter, and proper objections were presented at the joint hearing on March 22.

Committee to Consider the Appointment of an Executive Secretary.—Dr. FREDERIC E. SONDERN of New York submitted this report, which presented details as to the expenditures that such an appointment would entail. Owing to the expense involved the committee has voted to postpone the desired appointment.

Report of Committee on Legislation.—Dr. JAMES F. ROONEY submitted this report, in which he briefly reviewed the chief measures of importance to the medical profession introduced during the legislative session of 1921. These were:

1. The Compulsory Health Insurance bill which this year scored the whole gamut as had been predicted by him at the first hearing upon this measure in 1916, including unemployment insurance, invalidity insurance and old age pensions. At last the bill was introduced by a member of the party to which the measure belonged, the member being Mr. Orr, the Socialist. This bill had slept very quietly in Committee.

2. The various measures concerning the Narcotic Drug question. Of these there had been four. The first Lord bill abolishing the Department of Narcotic Drug Control; the second Lord bill reenacting the main provisions of the old Whitney law without provisions for any bureau to make rules and regulations; the second Smith bill, practically the same as the Cotillo bill of last year which would prohibit the prescribing any narcotic drug to patients suffering from addiction disease, permitting only personal administration of the drug by the physician, thus prac-

tically compelling the institutionalization of all persons afflicted with addiction disease or driving them to the underworld for their supply of drug. It required that practically all addicts should be committed to State, county or municipal hospitals or to private sanatoria or hospitals which had been licensed *ad hoc* by the State Department of Health. It furthermore required the keeping of records by physicians and official prescription blanks for every case in which a narcotic drug was dispensed for no matter what disease and in no matter what amount and for no matter what method of application or administration except it be for external application. It rescinded for the purpose of enforcement of the act the statute of privileged communications. After describing more in detail all the undesirable features of this bill, the report stated that the first Smith bill classed drug addiction among the infectious and communicable diseases presumably to give the same power to boards of health and health officers to commit and hold in isolation drug addicts as they now exercised under the same section in cases of smallpox, diphtheria and the other infections. This endeavor to so characterize drug addiction was well termed by the Commissioner of Health of the State of New York at the hearing upon these bills before the Governor as "sheer nonsense."

3. The Health Center bill somewhat modified from that of last year, but essentially the same, died in committee after a hearing.

4. The Chiropractic bill, which was reported favorably after a snap hearing on twenty-minutes' notice. The hearing was not publicly noticed. Through a clever maneuver the very capable legislative agent for the chiropractors through a second person handed the bill to Senator Wiswall of Albany who, without reading the measure, introduced it in the Senate and who in two days so amended the bill in order to require proper standards of preliminary and professional education on the part of those who sought to be licensed under the waiver clause of the bill, that the chiropractors at the Senate hearing appeared in opposition to their own bill. At this hearing Senator Wiswall accused them of not wishing to meet educational standards and thus not showing good faith. The bill was never reported by the Senate Committee and was re-committed in the Assembly on the second last day of the Session and thus died.

5. The amended Medical Practice Act, without the provisions for re-registration of physician, providing for prosecution of offenders against the law by the Attorney General instead of by district attorneys was swapped by its introducer for the Chiropractic bill through what seemed to Dr. Rooney an error of judgment, although done with the best intentions.

6. The bill changing the constitution and method of appointment of members of the Public Health Council which would put this most important advisory body into the field of local politics was defeated in the Assembly.

7. The bill for the purpose of authorizing osteopaths to report births and deaths and cases of communicable disease and giving them all the rights, privileges and immunities of regular physicians was killed in the Committee on Public Health of the Assembly.

It seemed important to the Committee that the medical profession should begin to consider seriously the menace involved to the public health, the public weal and the profession and evidenced by the continuous and persistent efforts of lay groups, highly organized minorities, in association with small but influential cliques of physicians. The end was to secure eventually complete control of the medical profession and ultimately to socialize it. The same groups that were interested in forwarding the scheme for Compulsory Health Insurance were now looking toward State Medicine, the entering wedge of which was the Health Center plan which was to be combined finally with Compulsory Health Insurance. Regulations as to the use of narcotic drugs and alcohol were merely the beginning of an attempt to control completely therapeutic methods. The various committees that had been appointed by national and State bodies to "investigate" these subjects apparently had had as their foremost requirement for membership thereon the proof of lack

of experience with the subject to be considered by them and their reports had always been entirely standardized and apparently written *ad hoc* by an interested group comprising not more than ten men in the medical profession and a couple of lawyers. Their investigations had not been unbiased, their findings had not been judicial, and their reports had largely been *ex parte* formalizations. These evils must be excoriated, the Society must be united, it must organize, it must educate the public or if it did not, so surely as the tide covered the sand bar, the profession of medicine would become the tool or instrument of forces existing to-day in the commonwealth, whose sole desire was power attained through absolute control of the medical profession. Unless a greater interest was taken by every individual member and especially by the officers whom the members elect in these matters which so directly interested and affected them they would very shortly be overtaken by a calamity not apparently deserved. At the time of the making of the present medical law in this State the medical profession and the other associated professions following them supinely agreed to provide funds for the administration of the law. The Legislature graciously agreed to this principle because it would cost the State nothing for, in this manner, protecting to a degree the public health, and provided in this law, that all moneys received should be paid into the State Treasury and that the Legislature should annually appropriate an amount sufficient to administer the law. Through these beneficent provisions the professions had paid into the State Treasury each year for the last ten, excluding this year, from three to ten thousand dollars more than the Legislature had appropriated back to them for the administration of the law, and this year would pay in a hundred thousand dollars more than was reapportioned. And still the Legislature would not report a bill increasing the salary of the Secretary of the State Board of Medical Examiners, a salary fixed fourteen years ago, in the sum of five hundred dollars in order to bring the salary for this office to correspond with that of the Secretary of the Dental Board. Was it not time for the professions to insist that they should not be taxed illegally and indirectly to pay money into the Treasury of the State that should by right go to the bureaus having in charge the administration of the law as was the plain intent of the statute? Some attempt must be made to increase the efficiency of the prosecution of offenses against the Public Health law. Outside of murder, no crime against the common weal of the State went so often unwhipped of justice as violation of this law.

The amount of money spent by the Society in prosecuting the work of its Committee on Legislation was woefully inadequate; it had never, so far as the Chairman could recall, exceeded seven cents per capita of membership. The chiropractors alone spent from twenty to fifty thousand a year to maintain their legislative lobby; there were less than a thousand of them and the State Society had nearly nine thousand members.

This report made the following recommendations: "1. That a Legislative Bureau be established permanently at Albany for the purposes set forth in the report of this Committee for the year 1919. 2. That action be taken by the House of Delegates upon the perversion of the statute, by the Legislature in not reappropriating moneys received from the professions, to the department of education for the purpose of administering the law. 3. That a committee be appointed by the House of Delegates to confer with similar committees to be appointed by other professional, educational and lay bodies for the purpose of amending the medical practice act in order to make its provisions effective and to modify its requirements as may be deemed necessary for the practice of medicine, both general and special. 4. That a committee be appointed by the House of Delegates to devise a plan for conducting public health education by County Societies for the purpose of creating a public demand for proper health law and its enforcement. 5. That a Committee be appointed by the House of Delegates for the purpose of prosecuting a real state wide investigation—not the closed chamber five hour stereotyped dictated sort—on the subject of narcotic addiction disease, and that their re-

port embody suggested changes in the present law both Federal and State that they deem necessary for (a) proper medical care, and (b) police regulation. 6. That the House of Delegates determine whether at Legislative hearing the presentation of the argument for the Society shall be made by and at the direction of the Chairman of your Committee on Legislation or whether any County Society may, irrespective of the opinion of your Chairman, present its view in opposition thereto. 7. That the use of personal influence in any way to defeat the legislative program of this Society subject any member so offending to censure by the Society."

Report of Special Committee on By-Law Amendment.—Dr. GROVER W. WENDE of Buffalo submitted this report which stated that the committee had made an investigation of the methods of representation operating in other State Medical Societies. Quite 80 per cent. of the organizations sending delegates to the American Medical Association replied to a questionnaire. A tabulation of the replies compelled the following generalizations: 1. That in every other State Society the representatives to its House of Delegates were apportioned among the constituent societies in proportion to their actual active membership, except that each constituent society was entitled to elect at least one delegate. 2. That such method of representation had been found to work satisfactorily, and 3. That such unit representation was fair and just to the membership.

The report discussed four propositions relative to methods of representation and recommended that no change be made in the present method of determining the representation of the constituent county societies in the House of Delegates to the Medical Society of the State of New York.

Minority Report.—Dr. DANIEL S. DOUGHERTY of New York presented a minority report which pointed out that under the present archaic method whereby the membership of the House of Delegates was apportioned by the State Legislature, neither the House of Delegates, the State Society, nor the constituent County Society had a voice in the actual membership of the House, and this membership might be changed at any time by political gerrymander. In a body which professed to be democratic and representative, as did the Medical Society of the State of New York, the only just and equitable method of electing delegates possible was that which was based upon the membership. These United States were founded on the valid and indisputable contention that representation and taxation should be in proper proportion; any deviation from this was virtually disenfranchisement and verges on autocracy. Above all, the power of regulating the membership of the House of Delegates should be in the hands of the State Society and not of the State Legislature.

The adoption of the amendment was earnestly recommended.

Report of the Counsel.—Dr. GEORGE H. WHITESIDE submitted this report, which covered the activities of the Counsel of this society from the period between September 1, 1920, and April 1, 1921. During this time there had been received by the Counsel 57 separate cases instituted before September 1, and since that time 24 new actions, making a total of 81 cases that had required the attention of the Counsel. Eighteen cases had been disposed of in favor of the defendants, and one case resulted in a jury verdict against the doctor. In the latter case an appeal was now pending. There were now awaiting disposition 62 cases. A classification of the cases presented showed that fracture cases were particularly hazardous to the physician, 19.4 per cent. of the cases being of this nature, while 18.2 per cent. were obstetrical cases. In the latter there was a double hazard to the physician for damages to the patient as well as by suit on the part of the husband to recover for the loss of his wife's services. The total number of cases based upon injuries resulting from the use of apparatus, such as x-ray, galvanic current machines for the administration of anesthesia, together with those due to breaking of a needle in lumbar puncture, etc., was about 16 per cent. These figures indicated a high degree of hazard in cases involving the use of such devices. A brief outline of each of the cases was submitted. Mr. Whiteside then submitted a supplementary report in which he showed that since assuming the

duties of Counsel he and his assistant had spent 50 per cent. of their time on this work, for which he had received on an average of \$31 per case or about \$1.45 per hour for his time. He showed how the cases tended to accumulate in an ever increasing ratio and the necessity for clearing the calendar. He also submitted a suggestion for combining insurance indemnity with malpractice defense. At the present time if a physician or surgeon carried indemnity insurance with an insurance company, in case of suit he could not have the assistance of the malpractice defense of the Society because the insurance company preferred to conduct the case itself. The indemnity benefit under this plan would be entirely optional with each man. Mr. Whiteside acknowledged that he had found difficulty in finding an insurance company ready to cooperate in providing this feature, but he confidently believed that the plan was feasible, and by it all malpractice cases among those who took advantage of the indemnity would be tried entirely by the malpractice defense of the Society. He estimated the cost of such indemnity insurance as \$18 a year for \$5,000 to \$15,000, which was about one-third the new rate for this type of insurance.

These reports were referred to their appropriate reference committees for consideration.

New Business.—A number of resolutions were presented, referred to the Committee on Miscellaneous Business, and reported back to the House during the session. Among these was a resolution presented by Dr. Joseph A. Blake of New York, urging the support of the Society for the Duell bill, Senate No. 1636. This bill was an act to incorporate the State Veterans' Relief Fund, which provided for the removal of the administration of relief to veterans of the recent war from political influences and placing it in the hands of a commission. This bill had passed both houses and was before the Governor awaiting his signature. The House of Delegates approved the bill and sent a telegram to Governor Miller notifying him of the action of the society and urging him to sign the bill.

A resolution was introduced stating that the National Anesthesia Research Association requested the Medical Society of the State of New York to petition the American Medical Association for such a section. The Reference Committee disapproved of this resolution, and Dr. Murray stated that the American Medical Association already had under consideration the matter of forming a section on anesthesia. The Section on Miscellaneous Subjects was being used to try it out and find if there really was sufficient demand to warrant the establishment of such a section. A motion to lay the matter on the table was carried.

Dr. MARK MILLIKEN of Ohio submitted resolutions from the House of Delegates of the Medical Society of Ohio urging that the right to practise medicine in one State be extended to all States, that interstate practice of medicine be made as easy as interstate commerce. The Reference Committee disapproved this resolution, but approved of that part of the resolution providing that the A. M. A. be urged to perfect a plan for interstate practice which should maintain the standard that now existed in the State of New York. The resolution submitted at the last meeting of the Society amending the constitution to increase the annual per capita assessment from \$3 to \$5, payable before June 1 of each year, was approved by the House of Delegates; also a resolution for a special tax of \$2 for 1921 similar to that levied in 1920, to be collected by the treasurers of the county societies.

Dr. GEORGE W. KOSMAK introduced resolutions to the effect that, whereas many interesting and valuable papers were read before the Society, frequently by distinguished visitors from other States, that deserved a wider circulation than could be given them by the *State Journal*, and whereas the publication of papers in the *State Journal* was sometimes long delayed, that writers of papers be permitted to publish their papers elsewhere without simultaneous publication in the *State Journal* if they so desired. The House of Delegates disapproved of this resolution.

Dr. EDEN V. DELPHEY introduced a resolution providing that the Medical Society of the State of New York was emphatically opposed to "State Medicine," and to any scheme for "Health Centers," "Group Medicine," and "Diagnostic Clinics," either wholly or partly

controlled, operated, or subsidized by the State or National Government and that the delegates from this Society to the American Medical Association be instructed to present this resolution to the House of Delegates of the American Medical Association at its coming session in June and to use every possible means to secure its adoption. This resolution was adopted.

Dr. NATHAN B. VAN ETEN of the Bronx introduced resolutions requesting that in the *Directory* Bronx physicians be accorded a separate listing as those of the other counties, Richmond, Queens, etc. This resolution was adopted.

Dr. WENDELL C. PHILLIPS of New York presented resolutions providing for the appointment of a committee which in cooperation with the Counsel should make a revision of the constitution and by-laws of the Society and formulate a policy for future guidance, which should be published in the official organ before the next meeting. He stated that he had been studying the methods of other State societies and thought the constitution and by-laws of the Medical Society of the State of Texas furnished a model. By that plan the funds of the Society were handled by a board of trustees. This resolution was adopted.

The Reference Committee disapproved of the recommendation for reapportionment of delegates and the House voted to make no change in the present method of representation.

Dr. WILLIAM FRANCIS CAMPBELL of Brooklyn submitted resolution calling attention to the campaign against cancer being carried on by the American Society for the Control of Cancer, requesting the Society to endorse and support this work, and urging physicians throughout the State to take an active interest in the campaign.

Second Day—May 3, 1921.

Election of Officers.—The following officers were elected for the ensuing year: *President*, Dr. James F. Rooney, Albany; *First Vice-President*, Dr. William Meddaugh Dunning, New York; *Second Vice-President*, Dr. William H. Purdy, Mt. Vernon; *Third Vice-President*, Dr. William D. Johnston, Batavia; *Secretary*, Dr. E. Livingston Hunt, New York; *Assistant Secretary*, Dr. Wilbur Ward, New York; *Treasurer*, Dr. Seth M. Milliken, New York; *Assistant Treasurer*, Dr. Charles Gordon Heyd, New York; *Speaker of the House of Delegates*, Dr. E. Eliot Harris, New York; *Vice-Speaker*, Dr. Dwight H. Murray, Syracuse; *Chairman of Committee on Scientific Program*, Dr. Samuel Lloyd, New York; *Chairman of Committee on Medical Education*, Dr. Joshua Van Cott, Brooklyn; *Chairman of the Committee on Legislation*, Dr. James N. Vander Veer, Albany; *Chairman of Committee on Medical Economics*, Dr. Henry Lyle Winter; *Chairman of Committee on Scientific Research*, Dr. Frederic E. Sondern, New York; *Committee on Prize Essays*, Drs. Edgar A. Vander Veer, Albany, Edward D. Fisher, New York, Charles Stockton, Buffalo; *Delegates to the American Medical Association*, Drs. William Francis Campbell, Brooklyn, James F. Rooney, Albany, Frederic E. Sondern, New York, Grover E. Wende, Buffalo, Thomas E. Chalmers, New York; *Alternates*, Drs. Henry Lyle Winter, Cornwall, Russell S. Fowler, Brooklyn. E. MacD. Stanton, Schenectady, Joseph B. Hulet, Middletown, James E. Sadlier, Poughkeepsie.

Resolution in Favor of First Lord Bill.—Dr. JAMES F. ROONEY stated that there were now four bills before the Governor awaiting his signature. He thought that possibly he was delaying his signature waiting to see what the sentiment of the Society was in reference to these measures. The four bills were the two Fearon-Smith bills and the two Lord bills. Dr. Rooney reviewed the substance of these bills (see Reports of Legislative Committee) and made a motion recommending that the Society put itself on record as favoring the first Lord bill, which wiped off the statute books all laws on the subject of narcotic drug control. After considerable discussion, this motion was carried and a telegram was sent to the Governor informing him of the action of the Society. On motion the other bills affecting narcotic drug control were referred to the Council for consideration and proper action.

Amendment to By-Laws.—An amendment to the by-laws was adopted making it unnecessary for the

House of Delegates to give notice at one annual meeting of the time and place of the next annual meeting.

On motion the selection of the time and place of the next meeting of the Society was referred to the Council with power to act.

GENERAL MEETING.

May 3, 1921.

THE PRESIDENT, DR. J. RICHARD KEVIN OF BROOKLYN, IN THE CHAIR.

The one hundred and fifteenth annual meeting of the Medical Society of the State of New York was called to order by the president, Dr. J. Richard Kevin.

Address of Welcome.—Dr. WILLIAM FRANCIS CAMPBELL of Brooklyn, chairman of the committee on arrangements, delivered this address. He stated that it was one of the functions of the chairman of the committee on arrangements to make a perfunctory address. The work of the committee was completed, the feast was spread, the committee bid them welcome and invited them to partake. They believed the function of a medical society need not be circumscribed solely by the personal activities of the members who attended. They had discovered a unique opportunity to interest the local community in public health, sanitation, and hygiene. He hoped the annual meeting in the future would be an event not merely for the profession, but would be sought and welcomed by progressive communities for the educational advantages which it conferred and the stimulus to higher civic ideals which it bequeathed its host. He trusted the meeting would demonstrate that the results of the efforts of medical science could be applied to the individual, the home and the community. They should feel that their efforts were well expended if this exhibit demonstrated that medical science was not something aloof from the community but was the very essence of communal idealism, satisfied never with things as they were but only with things as they ought to be. It seemed that that was the fine idealism that inspired all art, and science and literature—the passion of things as they ought to be, that was the keynote of medical science. Dr. Campbell said he did not wish to repeat the hackneyed formula of welcome, but merely to say that the Society of the County of Kings was honored by the presence of the Medical Society of the State of New York, one of the links that united the medical profession of this land in the great American Medical Association. It was said that the flesh of animals that fed exclusively was better than that of those that were cooped up. He was quite sure that the medical profession was far richer since it had acquired the peripatetic habit. This had been the means of bringing the influence of the Rochester Clinic, of the clinics of Cleveland, Chicago, and Baltimore to every town and hamlet, because the progressive physician fed exclusively. Dr. Campbell said they had come here for recreation, for instruction, to be blessed by the bishops of the profession, men not circumscribed by the narrow limits of their own parish but men whose domain was the limit of the world, the masters who would stimulate their professional work and their idealism. They had each come from their own Main Street, and if he might interpret them by his own personal experience he would say that in Main Street one often grew weary, in Main Street one sometimes lost his perspective, in Main Street one was not always the man he would like to be, so it was periodically necessary that from time to time they should pause by the way, to come to a convention like this to relight their lamps, to retrim the lights of their idealism, and to kindle their enthusiasm. If when they went home they were better men in Main Street their trip would not have been in vain.

President's Address—The Future Physician.—Dr. J. RICHARD KEVIN delivered this address, in which he said that in order to determine what should be the attributes, the function and the standing of the future physician, we must necessarily review the conditions and environments which had placed the present physician on his pedestal. Unlike the law of gravitation, the law of economics changed frequently. There was no form of matter in the world which did not change.

If all the changes in the economic and industrial world were to occur through revolution we would be constantly in a stage of confusion. We could not think of such a thing as standardization. It was many hundreds of years ago when the barber was the local surgeon, but even today his sign, which displayed white and red bars, was symbolic of blood and bandages. If one glanced over the wonderful changes in our profession in the past seventy-five years, it would be seen that just as the great achievements in medicine and surgery had advanced just so much had the States defined a higher qualification to practise the art of medicine and surgery. Even twenty years ago the preliminary requirements of the State to enter any recognized medical college were quite meager; and three years in college were all that was required for graduation. Today practically all of our medical colleges required an equivalent of four years college course before matriculation; then four years in a recognized and qualified medical college; and thereafter an internship in a recognized medical college. Thus one saw how progressively the State had advanced in its demands upon the doctor, before he was permitted to practise. The late John B. Murphy of Chicago, some years ago maintained that excessive standardization suppressed individualism, dwarfed genius, and created a standard doctor, with constantly decreasing instances of unusual talent. He believed that the medical schools of several decades ago fostered individualism, which resulted in a relatively larger number of men with unique ability. It had been said that the specific endowment of men varied in intelligence and ingenuity, and balanced judgment was a necessary constituent in the ore of mankind. To subject all this varying ore to the same process of reduction was to attack common sense and waste opportunity. However, the standardization of the qualifications of the present and future physician was too large a question to discuss tonight. Assuming that the requirements and qualifications of the future physician would not have changed, what were his prospects for the future? Would he be permitted to pursue his profession in an independent and progressive way, unmolested from without and contented within? Would he encounter on the one side compulsory health legislation and on the other State medicine legislation? We must remember that the physicians of this day were recognized as leaders in all great health questions. Unless we heeded the writing on the wall this leadership would fast ebb away. New economic conditions were bringing to the front a social welfare element which would soon dominate our health affairs unless their activities tightened the grip of leadership. Physicians were content to allow the departments of health and welfare to fight the big dangers which could only be successfully fought by the power of State, such as epidemic diseases, polluted water supplies, proper sanitation, better housing facilities, and the removal of filth from the cities, towns, and villages. He could see a change in the curriculum of the future physician. Relatively his functions would be: First, to conserve the health of the well; second, to detect, when possible, and arrest incipient disease; third, to restore the sick to health; fourth, to ease the comfort of chronic patients, and bring comfort to the old and feeble. The curriculum today was fixed mainly in the diseases having a definite pathology. It was to the diagnosis and treatment of these diseases that more thought was given. The courses that were given in preventive medicine, sanitation and personal hygiene did not begin to do justice to these subjects. Because of our deficiencies in these subjects, sanitary engineers and social workers had entered the field. Those who regarded the conservation of health as the foremost of human interest were far from content with what had been accomplished in preventive medicine. When we considered that at this advanced age we had failed to suppress scarlet fever, diphtheria, measles, whooping cough, and poliomyelitis there seemed to be good grounds for apprehension. The educational facilities of the future physician would have progressed so rapidly that he could predict great advancement in the near future so far as preventive medicine was concerned. In the future practice of medicine he saw an abundance of specialists, internists, surgeons, pathologists, etc. But towering over them all he predicted

that the family physician would have come into his own. He would take the child in its prenatal state; after its birth, he would see that the child would participate in the environment of health and that its nourishment should be abundant and healthful by his frequent examination. Due to the education of the future public, yearly examinations would be obtained. He would replace the public school inspector; the child's tonsils and adenoids would receive attention when required; its mentality would be classified, and its general health kept to a high standard. This would be productive in bringing forth better physically developed men and women in the future. The future physician would have acquired ampler knowledge in sanitation and hygiene and thorough knowledge of the psychology of character and habit. He predicted that the future physician would be educated to the necessity of having frequent thorough physical examinations, not through the pressure of the family physician, but rather through the knowledge of the patient. As an example of the past propaganda, consider what had been accomplished in dealing with tuberculosis. The improved results were not due to any change in treatment, but rather to the doctor obtaining the patient in the incipient stage of the disease. The future physician was already with us in the prenatal state. His path of usefulness lay entirely on the mercy of the physician of today. Should we remain indifferent to the attempted legislative barrier which was being constructed to limit his initiative power and thereby lessen his usefulness to suffering humanity? We must awaken to our duty, be ever alert to the harassing efforts to impede the progress of our profession today so that the arrival of the future physician would be unfettered by the chains of limitation. Should we be successful in maintaining the healthful, independent environment the arrival of our brother would be a joy and a blessing to future communities.

Annual Oration—The Future of Medicine in America.—Dr. LEWELLYS F. BARKER of Baltimore delivered this address, in which he said, in part, that he did not claim to have any special prophetic power, but would simply try to report how the coming period in medicine looked to one who, during the last thirty years, had been fairly close in touch with medical scientists, medical educators, and medical practitioners. Science, industry, social organization, and philosophy had been undergoing momentous changes in our time, but in no domain had the alterations been more marked than in medical research, in medical education and in medical practice. Indeed it was not an overstatement to say that they had been revolutionary throughout the world and, above all, in America. It would seem that an unusual opportunity for creative work now opened up before America. Men, money, and materials were here in greater abundance than elsewhere. Our duties and responsibilities were obvious. The failing hands of Europe had thrown to us the torch; let it be ours to hold it high. There were many evidences that the medical profession in America was keenly alive to existing opportunities and to present duties. All over this country preparations were being made for a great advance in science and especially in medical science. That the progress of the medical sciences was, to a very large extent, dependent upon the advances in the underlying sciences of physics, chemistry, biology, psychology and sociology, and upon the training of prospective medical students in these fundamental sciences precedent to their undertaking their medical studies proper was a lesson that had been well-learned in this country. Provision had been made for work in these basal sciences in our greater universities, in privately endowed research institutes, in government laboratories and in great manufacturing plants; in all of these institutions arrangements had been made for the prosecution of original researches in natural science subjects and for the training of young men in their methods while they also studied their principles. We must see to it that these opportunities were not only preserved but expanded. Careers in these branches must be made attractive and the numbers of men entering upon them must be increased. Institutions of this kind should be more liberally subsidized than they were now. Special institutes for intensive work in psychology, sociology, in psychobiology, in the study of human be-

havior and of industrial relations were urgently needed and would doubtless soon be provided. Without progress in the directions mentioned, the advance of medicine itself would be hampered, and those who were interested in the welfare of medicine should see to it that a knowledge of the need for these activities was widely promulgated. The medical sciences proper, both preclinical and clinical, had, since 1890, made great progress. In the majority of the States in the Union there were now institutes, more or less well equipped, devoted entirely to the subjects of anatomy, physiology, biochemistry, pharmacology, pathology, and bacteriology. Each of these institutes had at its head a director who devoted his whole time and attention to teaching and research in his subject. In many provision had been made for an adequate corps of assistants and for suitable technical help. In the near future, however, it would be necessary to make careers in these preclinical sciences more attractive to young men than they seemed to be now. Judging from the difficulty at present experienced in securing accessions to the staffs of these institutions, ways and means would have to be devised to make the positions more rewarding on the material as well as the intellectual and social side; for otherwise the necessary succession of preclinical scientists would be lacking. The domain waiting for tillage by these preclinical scientists was enormous in scope. Normal structure and function must become ever better understood in their chemical physical and biological details in order that pathological histology and cytology, pathological physiology, and pathological chemistry might continue satisfactorily to evolve. Those who were interested in the clinical sciences of diagnosis and therapy should, therefore, take an active interest in favoring the continuous development of the preclinical sciences in every legitimate way. Dr. Barker declared that he could not emphasize too strongly that the material and human needs in these scientific departments now urgently demanded serious attention. After referring to the growth of clinical science, he said that, after all, it was for the diagnosis of disease, the treatment of disease, the prevention of disease and the maintenance of the highest possible level of the physical, mental and moral health of the people that the medical profession existed and that the whole group of medical sciences clinical and preclinical, had been developed. It had been found that the methods of science were just as important in the pursuit of new clinical knowledge as in the prosecution of premedical and preclinical research. System and precision were just as essential in one domain as in the other. Facts must first be carefully collected, arranged, and compared; then they must be brooded over, in order that suggestions of interpretation might rise in the mind and, finally, these suggestions must be tested for validity before they were accepted as true or rejected as false. This was the method of science and the clinician used it just as did the physiologist or the chemist. Owing to the great extent of the clinical domain there had, as every-one knew, gradually developed a variety of medical and surgical specialties with corresponding concentration and intensification of the effort of particular workers. This division of labor had brought with it special difficulties and disadvantages, but, on the whole, the advances made in the clinical sciences by means of specialization had been astounding. That there would be a cessation of this tendency to specialization seemed unlikely; on the contrary the differentiation of workers would in the future, in his opinion, become ever greater, for men had found that mastery came through limitation of field and concentration of interest and effort. Coincident, however with this ever increasing division of labor, provision had to be made for the synthesis of results of the special workers into harmonious wholes. For this interpretative function men of wide training and sympathies, with comprehensive grasp possessing the so-called encyclopedic type of mind would be needed more than ever before to sift the essentials from the non-essentials, to arrange, classify and reduce to manageable volume, the total results of all the special workers. Contributors to the various forms of medical literature performed a most valuable service for unless knowledge came quickly and adequately organized so that it could be generally absorbed, the practising pro-

fession and the public would be wrongly deprived of benefits that should accrue to them. We had still far to go in this country before we should reach even the imperfect forms of medical communication that existed in certain countries in Europe before the war.

Dr. Barker then spoke of the improvement of medical education and the various factors that had been operative in bringing it about. At the moment medical education was confronted with a number of problems that pressed for solution. These problems were partly financial, partly matters of policy. Vast amounts of money could be used if available. Even if money were available, men could not at present be supplied with the training that was desirable to fill the new posts. The lack of men trained in the preclinical sciences was particularly alarming at this time, and the adoption of the whole time system in the clinical departments of many institutions would bring with it its own difficulties, those of finance, those of personnel, and those of adjustment among whole time workers and part time workers. For the welfare of the schools both types of workers would seem to be desirable in the clinical branches, and just what function each type of worker was to perform must gradually, through experience, be decided upon. The utilization of both whole-time men and part-time men in clinical work had in his opinion, many advantages over an exclusively whole-time or an exclusively part-time staff. It was of great help to the hospital to have certain men whose whole time and interests were given to the work of the institution, undisturbed by outside activities. Such men set a wholesome example of devotion to teaching and research and could help to instill the spirit or scholarship in the medical student. Certain types of men were happier in whole time positions that protected them from outside solicitation and set them free from the necessity of practising privately for income. The part time man was also an asset to the university clinic for he would attract clinical material to it, and would bring into the clinic along with the knowledge and experience gained in private practice a certain robustness and tolerance indicative of his wider contacts with outside life. He could exert a wholesome influence upon medical students who expected, later on, themselves to engage in practice for men were greatly stimulated by contact with seniors who had been successful in careers to which they themselves aspired. Furthermore many of the tasks of the clinic could be just as well performed by part-time men as by whole time men, with corresponding conservation of financial resources and of the time of the whole-time appointees. Both whole time men and part time men should invite constructive criticism of their work in order that the ideas of all might receive due consideration. A tendency to suppress constructive criticism did harm.

The whole time plan was so new that it was too soon to prophesy just what its effect ultimately would be upon the medical education, but he believed it was a step in the right direction and had come to stay, though he felt that it would be some time before we should have learned how best to adapt it to the needs of single institutions. If faculties would remember what a University really stood for and would arrange conditions in the best way suited to approach university ideals, taking care not to restrict the free development of the personalities of the scholars, they would have but little difficulty in arriving at a satisfactory solution of the problems of clinical teaching.

Certain subjects like neurology and psychiatry had not been adequately provided for except in a very few of our medical schools. A crying need at the present time was for a well endowed psychiatric institute in every university medical school. Then provision must also be made for graduate instruction and for continuation schools for practitioners who wished to do graduate work.

In discussing the future of medical practice Dr. Barker spoke of the relation of the general practitioner to the specialist as being one of the most difficult. The value of the group method of diagnosis was now recognized; but there were difficulties and dangers that confronted with the group practice of medicine which he had dealt with elsewhere. How the problem of rural medical service was to be solved remained to be

seen, but the medical profession should set to work to solve it at once. It might be wise to have county hospitals and a motor service to care for the county. It seemed likely that State medicine in one form or another was coming, and it would be well for the medical profession to see to it that its beginnings should be such as were best suited for the welfare both of the public and of the medical profession. The medical requirements of the public must be duly considered by medical men and a campaign of education inaugurated with the purpose of satisfying them in the best way.

As the medical sciences had advanced it had become ever clearer that in the future medicine would be largely preventive in function. As time went on humanity would find out how to secure well born children, and how to control the environmental influences, so that not only disease would be largely prevented but also more and more members of society would enjoy abounding vitality with a minimum of discomfort. We had learned how to prevent the spread of many infectious diseases that formerly caused large epidemics; malaria and hookworm disease were subject to control. Sooner or later we should learn how to prevent the spread of the exanthemata. The prevention of the acute respiratory diseases was more difficult, but the speaker was confident that the human brain would yet solve it. Dr. Barker then outlined some of the tasks in the way of the prevention of disease that remained to be done. There was the prevention of insanity, mental deficiency, and psychoneurotic states. It was astonishing how negligent we had been in attacking this problem in this country. It was reasonably safe to predict for the near future a great expansion of the United States Public Health Service and of the State and City Departments of Health throughout the country. Health centers with Red Cross support would soon be springing up everywhere. The number of medical men and trained nurses that would be needed in this work of protection of the public health was appalling to think of. One scarcely saw how they were to be provided. He thought likely that a dilution method would be resorted to. A relatively small number of highly trained men and women could make use of a very large number of persons who could be trained for certain special but limited tasks.

In closing Dr. Barker said it was our duty as members of the medical profession, and especially the duty of the family practitioner to take pains to educate the public regarding these needs of coming medicine and to urge laymen to do their part in hastening the advent of the better conditions that could be visualized.

(To be continued.)

Rabelais as Medical Man.—The recent labors of Montgomery in the United States, of Maurel and Gillard in France (the latter in his graduation thesis, and of Cumston in Geneva) show the appeal of this subject to the moderns. Among the older French medical students of Rabelais may be mentioned Brémont, Le Double, Chambard-Henon, and Martin-Dupont. Maurel, mentioned above, devoted his study to the travels of Rabelais in Italy, but Gillard, in his graduation thesis, which has recently appeared with the title "Rabelais the Physician," gives a more general review of his life and activities. The great man had the advantage of a fine classical education and could read the medical writings of antiquity in the original Greek. He was at an early period an accomplished botanist. After qualifying as physician he corrected proofs of the medical classics published by Gryphe and met Champier, the leading practitioner of Lyon, who got him the position of resident physician in the local Hotel Dieu. The salary was forty pounds annually with keep. For a time he became a sort of combination man to the bishop of Paris—secretary and body physician—but returned to his hospital position where his continued absences caused him to be investigated. He moved about a good deal and at times probably limited his medical activities to the capacity of private physician to some prominent man and his family, although at a late date he was at the head of a hospital in Metz. In the meantime he had become famous by his pen and we must seek for his medical activities in his books.—*Le Progrès Médical*.

Miscellany.

NEW BOOKS AND OLD.

V. BENJAMIN RUSH ON THE RELATION OF DISEASED TEETH TO ARTHRITIS.

By JOHN RUHRÄH, M.D.

BALTIMORE, MD.

LAST winter in trying to estimate Rush as a pediatrician, I went over his published writings, not a dull task by any manner of means, but in spite of his fluent diction, I came away with the impression that it was his imitation of the great father of English medicine that earned him the title of the American Sydenham rather than any very definite contribution to the advancement of medicine. Unless I err as a pediatrician, he certainly fell short of that other old Revolutionary worthy, Samuel Bard. What interested me most was Rush's account of medicine among the American Indians, and some of his clinical descriptions. Very much to the point is his observation in "The Relation of Diseased Teeth to Arthritis." Thinking that few know of this contribution, I am reprinting it in this place. It would be interesting indeed to follow up the history of teeth and arthritis, but time and space forbid for the present.

Some time in the month of October, 1801, I attended Miss A. C. with a rheumatism in her hip joint, which yielded, for a while, to the several remedies for that disease. In the month of November it returned with great violence, accompanied with a severe toothache. Suspecting the rheumatic affection was excited by the pain in her tooth, which was decayed, I directed it to be extracted. The rheumatism immediately left her hip, and she recovered in a few days. She has continued ever since to be free from it.

Soon after this I was consulted by Mrs. J. R., who had been affected for several weeks with dyspepsia and toothache. Her tooth, though no mark of decay appeared in it, was drawn by my advice. The next day she was relieved from her distressing stomach complaints, and has continued ever since to enjoy good health. From the soundness of the external part of the tooth, and the adjoining gum, there was no reason to suspect a discharge of matter from it had produced the disease in her stomach.

Some time in the year 1801 I was consulted by the father of a young gentleman in Baltimore, who had been affected with epilepsy. I inquired into the state of his teeth, and was informed that several of them in his upper jaw were much decayed. I directed them to be extracted, and advised him afterward to lose a few ounces of blood, at any time when he felt the premonitory symptoms of a recurrence of his fits. He followed my advice, in consequence of which I had lately the pleasure of hearing from his brother that he was perfectly cured.

I have been made happy by discovering that I have only added to the observations of other physicians, in pointing out a connexion between the extraction of decayed and diseased teeth and the cure of general diseases. Several cases of the efficacy of that remedy in relieving headache and vertigo are mentioned by Dr. Darwin. Dr. Gater relates that Mr. Pettit, a celebrated French surgeon, had often cured intermitting fevers, which had resisted the bark for months, and even years, by this prescription; and he quotes from his works two cases, the one of consumption, the other of vertigo, both of long continuance, which were suddenly cured by the extraction of two decayed teeth in the former, and of two supernumerary teeth in the latter case. (*Recherches sur differens points de Physiologie de Pathologie et de Therapeutique*, p. 353, 354.)

In the second number of a late work, entitled, "Bibliothèque Germanique Medico-Chirurgicale," published in Paris, by Dr. Bluver and Dr. Delaroche, there

is an account, by Dr. Siebold, of a young woman who had been affected for several months with great inflammation, pain and ulcers, in her right upper and lower jaws, at the usual time of the appearance of the catamenia, which at that period were always deficient in quantity. Upon inspecting the seats of those morbid affections, the doctor discovered several of the *molars* in both jaws to be decayed. He directed them to be drawn, in consequence of which the woman was relieved of the monthly disease in her mouth, and afterward had a regular discharge of her catamenia.

These facts, though but little attended to, should not surprise us, when we recollect how often the most distressing general diseases are brought on by very inconsiderable inlets of morbid excitement into the system. A small tumour, concealed in a fleshy part of the leg, has been known to bring on epilepsy. A trifling wound with a splinter or a nail, even after it has healed, has often induced a fatal tetanus. Worms in the bowels have produced internal dropsy of the brain, and a stone in the kidney has excited the most violent commotions in every part of the system. Many hundred facts of a similar nature are to be met with in the records of medicine.

When we consider how often the teeth, when decayed, are exposed to irritation from hot and cold drinks and all airs, from pressure by mastication, and from the cold air, and how intimate the connection of the mouth is with the whole system, I am disposed to believe they are often the unsuspected causes of general, and particularly of nervous diseases. When we add to the list of those diseases the morbid effects of the acrid and putrid matters which are sometimes discharged from caries teeth, or from ulcers in the gums created by them, also the influence which both have in preventing perfect mastication, and the connection of that animal function with good health, I cannot help thinking that our success in the treatment of all chronic diseases would be very much promoted by directing our inquiries into the state of the teeth in sick people, and by advising their extraction in every case in which they are decayed. It is not necessary that they should be attended with pain, in order to produce diseases, for splinters, tumours, and other irritants before mentioned often bring on disease and death, when they give no pain and are unsuspected as causes of them. This translation of sensation and motion to parts remote from the place where impressions are made appears in many instances and seems to depend upon an original law of the animal economy.

Hospitals in the Middle Ages.—Coudeyras, writing in *Le Progrès Médical* for January 15, 1921, xlix, 3, considers this subject under the following heads: hospices, hospitals, infirmaries, maladeries, leproseries, and lazarettes. The *hospice* was a sort of shelter or inn for the sick traveler and was an annex to a monastery. Sick pilgrims were cared for by the monks and made a voluntary offering on their departure. Certain orders of monks specialized in these hospices. Next are mentioned *hospitals* proper, usually styled *Hôtels* (or *Maisons*) de Dieu. From the XII to the XVI centuries these institutions abounded in France. The buildings were usually erected near a water course and were not isolated but grouped with other religious edifices. The building for the patients was a large single ward suggesting the interior of a church in which beds corresponded roughly to pews. The same interior architecture and decorations were seen—stained glass windows, pillars and arches, and ornamental façades. A chapel adjoined, so that the bedfast patient could hear mass. The most famous of the earliest hospitals were found not in the large cities but in towns which are now barely known to the casual reader. One of the largest was at Compiègne and measured 200 feet by 50. There is no mention of the number of beds. The proximity of a river

facilitated the disposal of excreta, etc. In the ward there were usually no distinctions of sex, but individual beds were walled off by wooden partitions or curtains. Hot water and vapor baths were installed and the hospital walls were whitewashed, sometimes annually. Heating was accomplished by means of huge chimneys. At a later period there were sporadic attempts to separate the sexes and to install confinement wards. *Infirmaries* seem to have differed in no respect from the hospitals, save that they were restricted to the care of the members of large religious establishments; however, one of the oldest had separate wards for the public. This was associated with the Cistercian Abbey at Ourcamp. A *maladerie* seems to have been nothing more than a small infirmary, a sort of sick bay for the members of small religious houses. *Leproseries* were at one time so numerous that nearly 2,000 existed in France alone. This maximum occurred during the XIIIth century. In these buildings the lepers were permanently interned until death. Civil death was ceremoniously decreed on entrance into the leproserie. The status was not unlike that of the Carthusian nuns. Only a few remnants of these numerous installations still remain. The *lazarettes*, despite the suggestion of the name, were not intended for lepers but were the analogues of our pest-houses—vast barracks of buildings used during severe epidemics. They were always burned down after the termination of the epidemic.

The original Academy of Medicine of Paris.—In celebrating the centenary of the present *Académie de Médecine* in Paris it must not be overlooked that this is not the first society to bear the name. On September 24, 1804, a number of medical men met at the Hotel d'Aligre to found a society under that name. The object was to raise the standards of the profession and advance the art of healing. The president, or, rather, director, of the new society was none other than the redoubtable Dr. Guillotin, who was unanimously chosen. Napoleon's permission was asked to use the adjective "imperial" in the title of the society, but this was refused. There were bimonthly sessions. The rent of 15 francs per session for the hotel was a hardship to the few members, and the society obtained from the Government the use of the building known as the Oratory.

New applicants were required to pass an examination in Latin, surgeons were not eligible as full members, and the well-known Sedillot was obliged to declare himself a physician to gain admission. Nevertheless the enterprise prospered from the start. The first general subject to come before it was the use of bark in intermittent fever. By 1808 there were 163 members of all classifications, although but 35 were active titular members, the remainder being honorary or corresponding. Dissensions arising, the society ceased its existence in 1811, or rather merged into a new one with Portal as president. The Society of the Academy, a separate body of men, continued its existence, despite the factional fight. Guillotin, its president, died in 1814. The malcontents of the Academy organized under the name of the *Cercle médicale*, and the two factions were reunited in 1819, retaining the name of the latter body. In the next year the present *Académie* was organized, with Portal as first president.

THE PROBLEM OF A PSYCHOPATHIC HOSPITAL CONNECTED WITH A REFORMATORY INSTITUTION.*

By EDITH R. SPAULDING, M.D.
NEW YORK.

THERE has been much discussion during the last ten years regarding the exact meaning of the term defective delinquent and the types of individual that such a diagnosis should include. When appropriation was made in the State of Massachusetts in 1911† for an institution for the defective delinquent, it was generally supposed that all those who had been misfits in the various institutions to which they had been sent, namely, the mental hospitals, the schools for feeble-minded, and the reformatories, would be found to be defective intellectually as well as emotionally and therefore would be fit subjects for permanent segregation on account of their intellectual defect. When it was found on closer study that many, although defective in emotional control, ranked high when psychometric tests were applied, considerable doubt arose as to the legality of the commitment of such persons, if neither insane nor intellectually defective, no matter how ill they were fitted, on account of their irresponsibility and their lack of emotional control, to be members of the community. Accordingly, certain examiners agreed that the term "defective delinquent," as they used it for diagnostic purposes, should include only those individuals who were intellectually defective as well as delinquent. This may be considered a restricted interpretation of the term, but it is, we believe, the only accurate one. Should the term be used to include all cases with a personality defect of some kind, there would be few in the entire reformatory population who would escape such a classification. When the term is used to include that heterogeneous group of individuals that for years have constituted one of the most difficult of institutional problems, it is a misnomer and leads to misunderstandings and a confusion in diagnosis. Such a group should be called preferably psychopathic delinquents, and the word defective reserved for those who manifest intellectual limitations not in the sphere of judgment alone, but according to accepted psychometric standards. It is this group, in

which a psychopathic hospital connected with a reformatory institution should be interested, and which was the object of our study at the hospital at Bedford Hills* during a period of over a year and a half.

The cases selected will comprise borderline cases of mental disease, such as manic depressive cases showing much instability but not in an acute phase, early cases of schizophrenic and cases of cerebrospinal lues that are not committable, psychoneurotic and neurotic conditions, cases of epilepsy, and the many that may be grouped under the general terms of constitutional inferior or psychopathic personality and who are also subject to psychotic episodes. Since such a hospital must necessarily be, in so uncharted a field, a research laboratory, there should be included, with the cases showing obvious nervous and mental symptoms, all problematic cases with marked conduct irregularities. Many cases will remain in the hospital but a short time and can be returned to the institution proper after a period of observation, but the majority of cases will be the very difficult ones that, because of their emotional instability and unadaptable traits of personality, find it impossible to maintain their equilibrium for any length of time in the midst of the main institutional group.

While it is of great help to the institution to have these unruly members removed from its midst, it is no easy problem to manage them for any length of time in a single family group in which they must of necessity continually rub up against each other's idiosyncrasies.

For eight months the experiment was tried of managing the hospital as nearly as possible as any other psychopathic hospital away from a reformatory institution might be managed. No punishment of any kind was resorted to, except the occasional locking of doors when situations grew too tense and threatened to get beyond our control. Every resource possible was offered to stimulate interest and much individual attention was given to the different patients to help them to form a more constructive attitude toward life in general and their daily problems in particular. In spite of all efforts, however, there was continual unrest, friction, irritability, and dissatisfaction that was as trying and unsettling for the patients themselves as for the staff.

Besides hydrotherapy, which consisted of continuous baths, shower baths, and wet packs, there was for the twenty patients whom the hospital accommodated, a department of physical training and

†Acts of 1911, Chap. 595, An act to provide for the maintenance at Reformatory for Women, the Massachusetts Reformatory and the State Farm of departments for defective delinquents.

an occupational department. A physical director had charge of out-door and in-door exercises and of entertainments in general. There was coasting and skating in winter, basket-ball, tether-ball, and croquet in summer, and volley ball, Indian clubs, dumb-bells, together with out-door tramping all the year round. In the occupational department there was basketry, weaving, embroidery, knitting and crocheting, rug-making, painting, carpentry, etc.

The most striking feature of the group was the widely differing personalities that were represented. One woman was an expert pickpocket who prided herself on her ability to steal from men better than any other woman in New York, with one exception. She had been alcoholic, a drug habitué, swore as easily as she breathed, was excessively irritable and had withal a keen intellect, a lively sense of humor, a dominating will, much vulgarity and a very penetrating, loud rasping voice. In the next room to her was to be found a very unsophisticated child of seventeen with an acute chorea, undernourished and anemic and meek and suggestible, seemingly a ready prey for the first patient. Again, there was a patient who for fifteen years had been a prostitute, who showed much delapidation of personality and who spent all her time trying to think up obscene words and jokes in several languages. If urged to do anything resembling work she would not infrequently lie down on the floor and scream; and exercise of any kind was entirely out of the question. Another patient was a colored woman who for years had associated with gunmen and who loved a good fight. In her personality make-up was to be seen the abandon of her race combined with much sentimentality and childishness together with great inflammability. Although a physical coward she was brave and audacious as long as she saw nothing in the hospital program to restrict her license.

It may be of interest to give here the following diagnoses that were made on the thirty-three patients and the eleven workers who were residents in the hospital. Among the patients there was one case of dementia præcox and one manic-depressive psychosis. These, with four unclassified depressions and a case of constitutional inferiority with psychotic episodes, were transferred to a mental hospital.

Thirteen cases were classified as psychopathic personalities. Of these, four were pathological liars or habitual fabricators. One of the four was also a border-line case intellectually; another was subject to attacks of migraine and showed great emotional instability; one had a multiple tic and one was feeble-minded and had latent lues. Four of the psychopathic personalities showed great emotional instability, one of these four having attacks of migraine, and another latent lues. Still another showed evidences of neurosyphilis and later on was transferred to a mental hospital; another showed marked paranoid traits.

Besides these cases there were three feeble-minded women with latent lues who showed much emotional instability; one manic-depressive constitution, an early case of paresis, two cases of chorea, one of torticollis, a case of epilepsy with a luetic infection, and two cases showing much emotional instability. Two cases that were admitted for ob-

servation and spinal puncture were discharged.

Among the eleven workers who were supposed to be more reliable than the patients, six were considered to have normal intelligence. Of these, however, two were luetic and one was very unstable emotionally. Four were feeble-minded, two of these having latent lues and one epilepsy; there was one border-line case who was also luetic.

Among the offences of these women were found four cases of grand larceny and nine of petit larceny. Twenty-two cases represented sex offences of various kinds and the remaining nine were for attempted perjury (1) receiving stolen property (1), possessing narcotics (1), disorderly conduct (1), vagrancy (2), and for contracting venereal disease (3).

While the group varied greatly from time to time, there were certain elements that were fairly constant; namely, much emotional instability with little power of inhibition, the play spirit in large measure, much childishness of the spoiled child type, strong primitive emotions, the clan spirit, and the antisocial grudge.

The majority of superintendents of hospitals for the insane, who have had in their care a group of four or five psychopathic women without facilities for separating them into different groups, appreciate the situation and recognize their inability to deal with them. Those who have not had this experience, however, understand with difficulty how the situation differs from that in the ordinary psychopathic hospital, or even in the ordinary boarding school attended by a difficult class of girls. I am going to describe a day at the hospital in order to give a picture of a few of the situations which, at the beginning at least, were daily occurrences, and which even with the best management possible and the greatest resourcefulness will, we believe, always be common.

A little after six o'clock in the morning loud screams are heard, piercing and agonizing, as if some one were being tortured by the methods of the Inquisition. The noise, however, emanates from Mary, the prostitute of fifteen years' standing, who thinks if she objects strenuously enough to her morning shower she will be sent to her room, thereby avoiding her morning's work, which consists in cleaning the bathroom. After this sound has gradually died down, but only after a prolonged argument between Mary and the nurses, loud talking and swearing by a very angry young woman is heard. A chair, basin, and water-pitcher are being hurled at a closed door, and the noise increases in such crescendo that it is necessary to go to the spot as soon as possible to discover the cause of the disturbance. It is found that the nurse, in giving out fresh towels, discovered that Mabel had an extra one that had been procured surreptitiously. The patient, a girl of nineteen who has always had a vicious temper and who occasionally warns us to keep out of her way when she is angry so that she will not injure us, implies that her personal rights have been infringed upon in not being allowed to have as many towels as she wishes. Undoubtedly a sense of guilt in having appropriated property to which she had no right accentuates her anger at being discovered. Hence, suddenly and without warning she strikes the nurse a fairly vicious blow, accompanying it with threats of further violence, delivered in a forceful language. When the door of the room is closed she picks up every available utensil to hurl against it.

At breakfast, at which this patient is in no fit condition to be present, being instead in a continuous bath, Grace, her boon companion, resenting the fact that her friend is in difficulties, deliberately makes uncomplimentary and insulting remarks about the hos-

pital, the food, and the nurses. She brings to the firing-line her entire force of profane and obscene language and is accordingly requested to leave the table. To this she replies that she will have to be carried out first and suits the action to the word by falling to the floor and kicking and screaming. After she has been removed from the breakfast group, all of whom have become greatly excited in the interim and have threatened to find similar outlets for their emotions, she proceeds to rip the sleeves of her waist from wrist to shoulder and otherwise deliberately tear her dress, later stating that the nurses did this in their maltreatment of her when they removed her from the diningroom. One nurse in particular on whom she swears everlasting vengeance, she accuses of giving her a knock-out blow under the chin. The following day, when brought face to face with this nurse, who laughingly says, "Why Grace, how could you say such a thing? You know that isn't true. Did I ever do such a thing as that?" she meekly replies, "Well, anyway, you put your fingers under my chin and lifted up my head."

After breakfast it is time for the biweekly treatments for venereal disease. According to laboratory tests, about forty-five per cent. of our patients were luetic and eighty-five per cent. had gonorrhea. Some of them had been sent previously to general hospitals for the treatment of these diseases and because they had refused to receive it while there they had been committed to the reformatory solely for the purpose of treatment.

Some of these patients have as little intention of receiving treatment now as they had then. Some of them represent borderline cases of mental disease and others are simply refractory through habit. Each group upsets the other. Persuasion is slow and discipline for the refractory not available. The hystericals and the epileptics are equally loath to undergo treatment, especially when that treatment consists in injections of mercury that may mean temporary discomfort. The antisocial group joins in complaining. Therefore, the clinic that would have lasted but forty-five minutes under different conditions, now lasts nearly two hours. Remarks like the following are heard: "I tell you I am not going to have any treatment this morning—I am sick of this damn joint. All you get is treatments, treatments, treatments. Can't you let me alone? Get out of here. Don't bother me. No, I won't go up there. If I do, she'll make me take it."

One patient, of a more playful disposition, is in hiding. After some search she is discovered sitting at the head of the attic stairs. Great shouts of laughter from her colleagues greet her discovery, followed by a demonstration of irritability and profanity on her part while she is being persuaded to descend. In spite of the fact that most treatments are eventually given, much effort has been expended in their accomplishment, and ingenuity and resourcefulness are often exhausted.

The housework, consisting of putting the rooms in order, making beds, sweeping and polishing corridors, and cleaning bathrooms and stairs, has been attended to, for the most part, by the nurses this particular morning, since many of the patients are incapacitated. Mary, our first patient, contrary to her expectations, was not sent to her room and so was fully able to care for her bathroom as usual. A new nurse, inexperienced with reformatory women but well versed in the ways of nursing, has just arrived to take charge of Mary's corridor. She discovers Mary hurling full pails of water over the bathroom floor and then attempting to mop up the flood. When the nurse remarks about what appears to her a rather unusual procedure and remonstrates with our patient, Mary insists that she is supposed to do it that way. Later, when asked why she took advantage of the nurse's inexperience Mary remarked, "I was just giving her a test to see if she was feeble-minded. You test us, why shouldn't I test her?"

The time now arrives for one group of patients to go to the occupational room and another to go out for exercise of some kind. Later in the morning the two groups change places, the first going out while the group that has been out of doors goes to the occupational room. One of the first group, Augusta, has taken a sudden dislike to occupational work of all

kinds. She had been working for some time on a rug that was to have been given away at Christmas, but becoming bored by the work as she frequently is by anything that lasts several days in succession, she swears that she will never work on it again even if it is not done by Easter. After several days' delay, during which time the loom is not in use, the work is given to someone else in order that it may be finished for Christmas. This results in great discouragement on the part of Augusta, who vows she will never again attempt work of any kind. This spirit is contagious. Others refuse, too, heaping abuse at the room and all in it, being led on by the clan spirit that makes all follow blindly where one leads. One patient, Vida, has been told by another patient that she will have to sew in the occupational room and make her own night dress as the supply is short. She leaves the room this morning swearing and insists she will never return. Although assured by the instructor that other work will be found for which she does not entertain such feelings of abhorrence, she insists, throughout her entire stay in the Hospital, upon anticipating that the sewing will yet be forced upon her and she can never be persuaded to remain in the occupational room for any length of time. This Vida is older than the others in criminological experience and she uses profanity as naturally as she breathes, and moreover almost as unconsciously and nearly as steadily. Furthermore, she is exceedingly unstable and her mental condition is such that it may be necessary to transfer her to a hospital for the insane. It is impossible to prevent her profanity. The slightest irritability brings on an emotional storm. In the meantime, and as a result of her influence, profanity becomes the fad of the hospital. All her followers—and she is decidedly a leader—vie with each other to see who can use the most. The habit is even adopted by those who have never before cultivated it.

The group to go out of doors is also out of sorts this morning. They don't feel like working in the garden. What do they care if the whole country is planting gardens, they don't have to; and what is more, they won't. One girl states that she has been sent here for nothing and that therefore the State owes her a living while here. Accordingly she intends to contribute nothing herself towards her maintenance. Another girl, who has just been operated on for tuberculous glands, and who has been ordered by the physician to stay on the sleeping-porch, refuses to leave her room. When every means of persuasion fails, and because of the fact that she is losing ground, it is thought best to insist on her obeying orders and carry her out. Whereupon, as she has never in her life been made to do anything she does not like, she retaliates by trying to trip the nurses up, biting and kicking, like a naughty girl of five, but with the strength of a grown woman. This proceeding is accompanied by screams and wails that can be heard nearly a mile away. Upon reaching the porch she throws herself down on the cold floor and continues the crying, so that for the peace of the whole neighborhood she has to be taken in the "quiet room" where she stays until the paroxysm passes. After this episode, the patient writes a long letter of repentance, in which she promises from now on to be good and to help those who are trying to help her. A few days later, however, a similar performance is likely to occur.

In the meantime, loud and angry voices arise from the kitchen where our so-called workers, also reformatory girls but supposedly more stable than the patients, are attending to the cooking and laundry. Rushing to the scene we find two angry colored girls attacking each other with the clothes stick and the stove lifter, respectively. Attempting to separate them is as dangerous as interfering in a dog fight. However, it must be done and one girl is finally extirpated, led upstairs and persuaded to allow her temper to cool down in a prolonged bath while the other is induced to remain in her room for the present. The superficial cause appears to be that Florence refused yesterday to help Martha remove the clothes boiler from the stove. Martha, not liking to risk a second refusal, applies this time directly to the matron for help. It angers Florence so much to have the matron know of their disagreement that she loses her temper and strikes her

friend. This, however, is Martha's side of the story, and we learn from other sources that Martha has a deep affection for Florence that has recently been discouraged by another of Florence's admirers. Martha has a mortally jealous disposition and moreover, a record of quarreling with everyone with whom she has worked, so that constant changes have been necessary in order to maintain any degree of peace. The laundry, however, is a large one. It must be finished this week and today is Friday. There is no one among the patients who can act as a substitute. These two must return to their work. But in this situation emotions of the most primitive nature have been aroused. There has been friction for some time and anger and jealousy so keenly aroused do not subside immediately. We try persuasion. Florence, a large, rather masculine type of negress, says ironically, "I am afraid to go back. I might get hurt and my face injured and then how would I look?" Later she says, "I guess we just can't get along together." Nothing more can be obtained from her regarding the cause of the disagreement or the prospect for the week's washing. Furthermore, she is not at all sure that she will not repeat the attack and even kill her opponent at the first opportunity. Still, that laundry must be finished, so they are told that they must return for the present but that some adjustment will be made in the near future. It is now quite apparent that they will probably never be able to work together amicably. This afternoon when the kitchen is unoccupied the young women return to their work with an accompanying nurse who stands in readiness to separate the two tigresses if the war should break out afresh. Primitive fires of that kind do not die down, however, and continued friction ensues until it is possible some days later to make a permanent change in the laundry force.

At the dinner hour Alema makes a remark detrimental to the food, that this time applies to the cook rather than to the management, whereupon Aggie, the cook, remarks that it is all very well to criticise the hospital and the nurses but she needn't think that her fellow prisoners are going to stand for criticism of themselves. A racial argument ensues, during which one girl rushes to her room in tears and the other is invited to go to her room on account of her disturbing actions and abusive and profane language.

The rest period of an hour after dinner was at one time taken on cots on the sleeping porch with one of the nurses reading aloud. This, however, appeared to be the cause of so much friction among our extremely irritable and sensitive population that it was thought best for the girls to spend the period alone in their rooms. This is the only time during the day when the room doors are locked, except in cases of emergency, and the effect on the patients of being definitely separated during this time is good. Without the lock and key the rest period is replaced by a time for much visiting in the corridors and at different doorways, which when interfered with results in renewed outbursts. The sex proclivities of these women must also be recognized, and, while nagging and apparent supervision must be done away with, they must be closely watched. The rest hour, then, in spite of our efforts to make it a real rest hour, is today rather disturbed. Still there is no serious outbreak and except for the sobs of one patient who curses the institution that prevents her from seeing or communicating with her lover, and the replies of others that come from various rooms, some sympathetic and some scolding, it may be said to be quiet.

In the afternoon some workmen arrive to put in electric lights. This is most disconcerting to the patients and every conceivable ruse is resorted to that will give them an opportunity to show off in the workmen's presence. When asked to do a simple task, one retorts "Go do it yourself, do you think I'm your slave? We'll show you nurses who's boss about here." Another will cleverly pick the workmen's pockets in passing (even while a nurse is in the immediate vicinity) obtaining matches and tobacco, as we learn afterward, with which to regale herself in the midnight hours.

Later in the afternoon a patient who has been much depressed since her entrance to the institution, because of what she considers unjust confinement, and who has been disturbed during the day, laughing loudly or wail-

ing, as the case may be, now becomes infuriated because a nurse has dared to bring her another eggnog. Being disgusted with the liquid diet on which she is kept on account of some gastric disturbance she throws the eggnog, glass and all, across the room, laughing with much glee as she does it. Later she overhears a remark made by another patient which she considers detrimental to her race, and, becoming much excited, she tears her hair and screams to the full capacity of her lungs. The excitement continues and as prolonged baths appear to have an undesirable effect it is decided to put her in a pack. At this she appears to be terrified and as she promises to be quiet, the preparations are discontinued. A half hour later, remembering again the insult, the screaming recommences. She is taken to the "quiet room" and given the pack, the whole force being required to accomplish it. After struggling at intervals for half an hour, she succeeds in getting out. However, she is now willing to go into one again without resistance and is decidedly helped by its sedative influence.

In the recreation room in the period before supper (the occupation groups and the out-door groups having had periods in the afternoon similar to those in the morning), Mamie, in order to draw attention to herself, begins without apparent provocation, to see what she can accomplish in the use of profane and obscene language. Vida, who has known her "on the outside," and who knows only too well the language capacities of both, is irritated beyond control by such unproductive language and suddenly attacks her with her own weapon, pouring forth such a flow of undesirable phraseology that Mamie, famed as she is for such talk, is stunned into silence. Vida, delighted at her achievement, laughs loudly and feels that the joke is such a good one that the doctors must certainly be told so that they also may appreciate it.

Let us suppose that supper is accomplished today without incident. In the recreation room afterward there is card playing in one corner, with a nurse making up one of the four, while the gymnastic teacher is showing some of the others some new dancing steps. A new patient has recently arrived. She has been looked upon with suspicion by the others, who fear that she will "rat" on them, telling their secrets. Many insinuating remarks have already been made in her presence and the newcomer, who in truth is anything but a worm, is about to turn. Enraged suddenly by a remark she believes intended for her, she sends the pack of cards she holds in her hand flying across the room at the speaker. It misses the target but hits another girl in the eye. The victim swears eternal vengeance and will have her blood. They grapple. Girls and nurses fly to the rescue. They are finally separated but most of the patients have to remain in bed the next day as a result of the various blows and injuries that they have received. Again the continuous bath is used and the attacked girl, who has been tearing her hair out by the handful, finally quiets down and asks that she may be allowed to spend the night in the "quiet room" in order to be spared any further noise and excitement.

Bed time comes. The excitements of the day make all the patients very talkative. Several are afraid to have their lights put out and are given permission to keep them lighted. Others of less nervous temperament do not wish any one to have a privilege that they cannot enjoy, and they sit crocheting or finishing some bit of embroidery that will bring a slight remuneration, refusing insolently to have their lights put out until a late hour, a fact that naturally enough increases their irritability the following day. And so our hospital day at length draws to a close.

It is well known that some of the most difficult cases found in penal institutions have never responded to disciplinary measures. It is these cases that are not infrequently transferred to hospitals for the insane, where some of them do well, making it appear that cases of this nature may be treated as mental cases with good results. Whether or not such treatment could be successful with a group of this kind, either apart from an institution where

discipline must necessarily be a factor, or in some other experiment connected with a disciplinary institution, we are unable to say. We can, however, show the factors that have complicated our own experiment.

While dealing with a reformatory group, and admitting the various problematic cases to the hospital for study, there will always be individuals who show no marked mental abnormality, but who, because of certain traits of character such as extreme childishness and excessive egotism, take advantage of the knowledge that no punishment or deprivation of privileges will follow, no matter what disturbance they may cause. They voluntarily instigate as much trouble as possible to try out the new system, and cheer over the fate of their fellow inmates in the next cottage whose conduct is controlled by other methods. As can readily be seen, this license, either in the form of riotous behavior or merely the intentional infringement of any rules laid down for the rest of the institution, has a most disastrous effect on the morale of the neighboring cottage.

The fact that the girls feel that they are being treated as *patients*, possibly of a mental nature, arouses their suspicions and touches a sensitive point that is perhaps a half-knowledge of their own instability. The entire group dub the hospital a "nut house" and surround it with all the suspicions and prejudices that are felt among the laity for hospitals for the insane. "If you go up there they'll operate on your brains" is commonly heard from the campus. The fact that the hospital patients are allowed more freedom and are not corrected to the extent that the reformatory inmates are for minor details, simply enhances this impression, and they are frequently heard to say, "Well, if the other girls consider us nuts, let's live up to the reputation."

It sometimes seems as though the psychopath has a more or less conscious sense of inferiority, when she compares herself with her reformatory friends who have more stability than she has, for which she tries to compensate by accentuating the recklessness and abandon that is natural to her. When the same patient is sent to a hospital for the insane and suddenly finds herself on the disturbed ward in the company of extreme mental cases, the feeling of inferiority is to a certain extent replaced by one of superiority. She realizes for the first time what complete loss of control means and she uses every effort to remain in the superior rather than to sink into the inferior class. One of these girls will say, "It made me realize what I was doing and what would happen to me if I kept on, so I just kept out of trouble."

Again the more abnormal a girl is the more suspicious she often is of any kind of mental hospital, and when she knows that it has frequently been necessary to transfer patients from this building to a hospital for the insane, she fears intensely that this is indeed but a stepping stone to such a hospital. The close relationship that is necessary in such a group as this only accentuates the unpleasant impression made by the transfer of a single individual to whom they have become attached. It is as though one of their own family had been transferred from their midst to a hospital for the

insane. Furthermore, the delinquent woman as a rule considers a prison Heaven when compared with a hospital for the insane. A patient will say tragically, "She has gone, and her young life is blighted. She wasn't insane. She had a good heart. I'll be the next to go, I know. You are just taking your time."

All this may serve to suggest the amount of re-education that must take place in reconstructing the patients' mental attitudes. Some of their fears, of course, can be allayed in the course of time, but it is difficult to maintain an atmosphere in which such fears do not predominate.

Another complication results from the fact that in such an institution it is necessary to rely on the more stable reformatory girls for the work of the hospital. The patients themselves are too unstable to be depended on. It is too expensive, and in other ways undesirable to employ workers from the outside. But those who are familiar with the reformatory situation nowadays know that the tendency of the judges is to place the more dependable girls on parole so that the reformatory population is made up largely of the most difficult cases that go through the courts. For this reason even the workers are none too stable and are kept up to the best standard of the institution with difficulty. This means that a standard of behavior will be required of the workers that is not possible with the patients and the double standard is at once a source of difficulty. The question may be raised as to whether discipline in any form is necessary in such an institution. We gave the experiment a trial and were not successful without it. The friction was constant and the hospital morale sunk to its lowest level.

The following incident may serve to illustrate what became only too common an occurrence. The cook, Louise by name, one of the colored inmates of the reformatory, usually had her room cared for by one of the patients. As she was over-critical of the results and frequent quarrels ensued, one after another of the patients refused to do it, and the task finally fell to one of our well-paid nurses. One morning the nurse allowed a few cracked nuts to remain on Louise's table supposing them to be considered of value. Later in the day an irate colored woman called the nurse to account for her negligence in the most insolent manner possible, adding that she had found a few hairs on the floor on the day previous and that such inadequate care of her room must not continue. Had the woman been an irresponsible patient, such an incident would have had no significance, but coming from a supposedly normal individual on whom the hospital was depending for its daily sustenance, and who could neither be treated as a patient, dismissed as a cook, nor disciplined, it and its sequelæ became serious. Not only did it express to a great extent the result of freedom allowed other inmates who were patients which had been quickly converted into license, but furthermore, coming from a so-called "worker," it aided in influencing in its turn the patients. Continual criticism of everything was common and no sense of responsibility could be aroused as one retort to every appeal was—"We shan't be punished, so what do we care? If we don't want to work or behave, we won't have to."

The prevailing idea in the hospital at one time was that the nurses were "too d— fresh" and that they must be put in their proper place and shown what they were there for, namely, to do all the work and wait on the patients.

The question of what discipline is, and how it may be administered is a subject on which volumes might be written. It is only possible to say here that we have found that a definite set of rules, correlated with a deprivation of privileges, administered always from a therapeutic point of view, even though by a layman, was very helpful in influencing the whole atmosphere of the hospital. There are undoubtedly cases in which exceptions must be made, but it is much easier to make exceptions in disciplinary measures in a few cases than it is to control the emotional reactions that occur in the psychopathic patients in general as a result of the license that follows when the disciplinary measures that are needed by the majority are suddenly withdrawn. We might say that the condition which resulted at the beginning of our experiment from bringing a certain class of difficult patients from a disciplinary environment, into a hospital atmosphere, suggested strongly the chaos that existed during the reconstruction period after the Civil War, and the revolutionary conditions that have followed the great war.

In studying the best methods of attacking the problem of the treatment of the psychopathic delinquent we sought the council of various eminent psychiatrists. One argued that, as many of these women represented primitive types, they should be allowed as much as possible to seek their own level, instead of having forced upon them a degree of civilization to which they were unable to conform. However true this may be theoretically, the practical result of following out such a method would be a Bedlam in which it would be difficult to formulate a constructive plan of any sort. With such a theory the progress or amount of civilization necessary to catch up in the least degree with standards of the present day, would take a period of time, covering several generations. The most rational method of attack, we believe, is, as far as possible, to reduce the environment to the simplest possible factors, to make it correspond rather to the environment of the child than to that of a primitive race. In this way, if the environment can be reduced to its simplest factors, the individual can begin with the situations he should have learned to face as a child. Gradually his responsibilities can be increased until as a reliable member of society his energy is finding adequate constructive outlet instead of exploding spasmodically at the slightest obstacle. In order to carry out this idea, it was the aim of the hospital to maintain as peaceful a level as possible in which outward irritation or disturbing influences were reduced to a minimum, in which there was a certain repression, if you will, of the most primitive characteristics, but at the same time a corresponding outlet of energy of a constructive nature. In other words, while an effort was made to discourage the loud laugh which, instead of being a healthy outlet, is frequently, if continued, the forerunner of an emotional explosion, which it is impossible for the patient herself or for anyone else to control, at the same time a variety

of interest was continually furnished, and the attention, as in the case of children, was diverted to something of a constructive nature.

Aside from the hospital spirit, the following resources were available for reconstruction:

Physical.—The women were first put in the best physical condition possible. A special requisition was made in the budget for extra food, such as milk, eggs, etc., that might be used to correct conditions of malnutrition. Funds much greater than were then available for the treatment of venereal disease in the State institution were provided for its intensive treatment. Physical defects, such as poor vision, carious teeth, etc., were corrected. A physical instructor had charge of the girls certain hours throughout the day, supervising the outdoor exercise as has already been described.

Mental.—Prolonged baths were found to be both popular and helpful, and their use was considered a privilege by the majority of the patients. Wet packs were used in acute excitements. Only in such a small group as this can the individual attention be given to each patient that is necessary in helping her to adjust herself to her environment, and gradually to assume responsibilities never before accepted. Such treatment includes the painstaking analysis of the individual through first winning her confidence and later unearthing her complexes and helping her to reconstruct the available material in her mental make-up.

Educational and Social Resources.—These included school work, stenography and typing and the occupational work already described. Among the social activities of the group were short plays and many small entertainments. The amount of attention and strain accompanying the acting of a small play is more than such a group of unstable individuals can stand. There ensues usually an emotional reaction that makes such attempts undesirable. For this reason the entertainments were made as simple as possible.

In order to stimulate individual initiative and promote self-reliance and to inculcate a spirit of cooperation, a club was organized. Though it is recognized by those who have had the most experience in self-government that a group such as ours can gain little, if anything, from such procedure, it was possible to organize a club that represented an effort to adapt to our own very variable group the idea of self-government, used to such good advantage in more reliable communities. The name chosen by the girls was "The Peacemaker's Club," the seemingly ironical title being the result of their own consciousness of their constant irritability and continual fighting. Later on, a system was evolved that was a combination of the campfire organization and a well-known credit system. However, neither of these plans was sufficient in itself to stimulate coordinated effort among the patients and any results obtained were too short-lived to be of much value.

It is interesting to see the attitude of nurses and teachers, who are confronted by a situation such as ours, after years of work attended with much success in hospitals for the insane. They approach the problem with a knowledge of their previous success, and much to their surprise discover before them an entirely different problem.

One nurse, who had been of inestimable value in the management of mental patients, said, as she was leaving in dismay before half her allotted time had expired, "But I cannot help you. You don't want me. What you want is a disciplinarian. I have never met anyone in my years of experience who has responded so little to kindness as these patients." It is true, I believe, that we needed a disciplinarian, but that was only the smallest part of our need.

A teacher, who had had years of experience in interesting successfully the patients of a hospital for the insane, said, "I have certainly had the conceit knocked out of me. I didn't dream, in spite of what was told me, that it could be so difficult. Anyone who can manage to hold their interest and attention has a hard undertaking before her."

As we have already stated, the attempt was made to introduce the routine of a true psychopathic hospital as far as possible without the use of disciplinary measures of any kind. After trying for many months to find some way of stimulating initiative and a constructive independence without discipline, the attempt was finally abandoned and a disciplinary officer was appointed to take charge of situations that seem to warrant it. Her sympathetic understanding of the women brought out their best rather than their worst side, and made of discipline *per se* an added asset in furnishing a temporary prop to start these unstable and inflammable women on a progressive rather than a retrogressive journey. One of our most difficult girls, when trying to sum up courage to have a spinal puncture performed, said of this very matron, "Call Miss R. I don't know how she does it, but she can make me do anything." And, "Oh, well, no one can be cross with Miss R."

Conclusions.—Those who have dealt with a group such as I have described in the midst of a larger and, in itself, a difficult group of emotional, unstable persons, either in a hospital for the insane or in a reformatory institution, have realized for years the need of an institution where such patients could be segregated in order to promote the stability of the larger group and also to give to the few the amount of outlet and individual attention necessary. That there is such a need is obvious. But that it can be met by placing such individuals together, at least in a single group, is not yet proved. The problem, which will vary always with the individual members of the group at a given time, may not be solved for many years to come.

The chief function of such a hospital connected with a reformatory institution should be to differentiate types. In the initial examination made of each woman on entrance to the institution any cases needing immediate transfer to a mental hospital should be recognized before they join the general population of the institution and should be sent to the appropriate institutions without going through the psychopathic hospital. While this number is small, being in our experience but 2 in 100, it is of much importance. Cases doubtful in nature should be sent to the hospital for a period of observation. The majority of cases, however, that are recognized as being markedly unstable at entrance belong to the hospital throughout their entire residence in the reformatory. It is by removing the

more unstable ones from the general population that the institution proper is given a chance to maintain a higher standard in morale and the psychopathic individuals themselves are given the best chance to maintain their highest level. The hospital should also be equipped to take for study and observation any patient who presents a special behavior problem in the institution proper.

It is in the management and treatment of the resulting heterogeneous group that the real difficulty of the problem lies, because a fairly stable background is necessary as a foundation for reeducational procedure. The most important factor then consists in finding a social level into which they can best fit so that as much effort as possible can be expended on their individual reconstruction. This reconstruction of personality should consist, generally speaking, in efforts to socialize their egotism. It should include any therapeutic measures that will benefit the physical condition of each woman, the stimulation of healthy interests and activities, and the unearthing of mental conflicts that have kept the personality from developing beyond infantile levels; and find ways to counteract feelings of inferiority, to sublimate primitive desires, and build up the weakest points in each personality whatever they may be.

418 WEST TWENTIETH STREET.

THE SCIENCE OF LOGIC VERSUS INFLUENZA.

BY JOHN J. HURLEY, M.D., F.A.C.S.
BOSTON, MASS.

IN the Field of Thought embraced by the Science of Medicine there is no such thing as metaphysical certitude. The certainties of to-day are the doubts of to-morrow. In this realm there is no place for dogma or ex-cathedra speech. In the final analysis practically every medical question remains debatable. The writer recognizes the obvious. He has hesitated a long time before presenting this article to the medical profession. Just how long will appear from the following. This paper, conceived in 1906, was first drafted in 1916, was vamped and revamped as events demanded, partly to keep it up-to-date, but mostly to tone down its style, against the possible charges of dogmatization and aggression. As it is presented to-day it represents the irreducible minimum, the *sine qua non*, of the writer's argument. If in spite of this it remains unusual in form, and too vigorous in language, he craves the reader's indulgence. He prays him to eliminate mentally these admitted personal defects, that he may concentrate on the larger issue involved. He reminds him that in the years 1918-19 8,000,000 souls crossed the bridge from Time to Eternity as a result of the subject under discussion. It is extremely important that these dead shall not have died in vain. No avenue of Hope, however seemingly remote, should remain unexplored.

The writer feels that under these circumstances his request for the reader's toleration will be granted.

In the year 1906 the writer began the study of the influenza problem. The following conclusions are the result of this study: (1) The medical prob-

lem of to-morrow is the sanitation of the nasal sinuses. (2) The search for the causative organism of an unknown disease should always include the mucosa of the nasal sinuses. (3) The disease influenza does not exist. (4) Nasal sinusitis, a well established respiratory disease, at the gateway of the human economy, is the only respiratory disease which has not a chapter of its own in the general text-books of medicine. Why is such an important disease so omitted? (5) The burden of proof is upon those who assert that a nasal sinusitis, at any time, under any circumstances, is a complication. The writer does not exclude dental conditions from debate. (6) For anatomical reasons it would be better to use as a generic term, the expression "infection of the lateral nasal wall," reserving the expression "nasal sinusitis" for specific diagnosis. (7) Putting aside the interesting question of the lymphatic drainage of this area, the nasal sinuses stand in direct venous connection with the right heart, by three main routes—the facial vein, the ophthalmic vein, and, through the foramen cecum, the coronary and longitudinal sinuses. What this means to the lungs and brain is self-evident. (8) This blood-supply and the phenolsulphonephthalein test, to be described later, have suggested to the writer the following addition to the treatment: If the proper therapeutic agent could be provided, be it bactericide or serum, the ideal site for injection would be the lateral nasal wall, and preferably the inferior turbinate, because of its vascularity. The writer would hope in this manner to short-circuit the infection at the source, and also to follow it through the system on its own elected route. (9) The diagnosis of nasal sinusitis is never eliminated until it is ruled out by the microscope. This fact is to be borne in mind in the study of non-secretory infectious diseases. (10) One attack of nasal sinusitis does not protect against a future one.

In this paper the writer proposes to analyze the disease influenza in the cold calm light of Formal Logic.

Logic is the science of the laws of thought. It is the science of right reason. It holds no brief beyond the grave. On every human question requiring solution the science of logic supplies the ultimate "why?" and "wherefore?" which reason demands. It is the science of all sciences. Upon it all other sciences are based.

Every science has its primary laws or axioms. If logic is really the science of all sciences, we must find in its first principles that which is the foundation, not of logic alone, but of all other sciences. Whatever be the subject-matter, out of all things in heaven and earth about which we think, those first principles must be accepted as supreme, irrefragable, universal, immutable, eternal. The science of medicine is based upon these principles. Therefore the truth or falsity of a medical idea will be determined by this court of first principles. The "influenza" problem must acknowledge this jurisdiction. The disease "influenza" must stand or fall by the verdict of this court.

Before we enunciate these first principles, let us consider proof. There is a double method of proof. We may prove a thing either directly and positively, by showing from certain positive principles respecting it that it is so, or indirectly and negatively, by

showing the impossibility of any other alternative. It is clear that positive or direct proof is better argument than negative or indirect proof. The former teaches us immediately what things are. The latter teaches us what they are only by an inference from what they are not. Positive proof, moreover, not only teaches us what things are, but gives us an insight into the reason why they are so. Negative proof in its final result never gets beyond the conclusion that something that was in dispute is really true.

One further word before we take up the real subject matter of this paper. Everything must either exist in itself or it must inhere in something else. In the first case it is a substance. In the second case it is an accident. Accidents are nine in number. When added to substance they form the ten categories of Aristotle. If we say anything about some object which has an existence of its own, we must speak either of its quantity, its quality, its relation to surroundings, of what it is doing or what is being done to it, of the place or time of its existence, or of its position or external belongings. These categories are enumerated in the following distich:

Summa decem: Quantum, Substantia, Quale,
Relatio, Actio, Passio, Ubi, Quando, Situs,
Habitus.

With these things premised we may proceed to lay down in order the principles or primary laws of logic, and not of logic only, but of all science and of all truth. These laws are *a priori* propositions which no rational man may deny without committing intellectual suicide. It is not the province of this paper to explain them. A mere statement of them with their concurrent application to the influenza problem is the writer's objective. (1) The principle of contradiction. (2) The principle of identity. (3) The principle of causation. (4) The principle of excluded middle.

1. *The Principle of Contradiction.*—The foundation of all proof, direct and indirect. First and foremost, implied in and underlying all other principles. It may be enunciated thus: Nothing can at the same time exist and not exist; influenza cannot at the same time exist and not exist.

This principle is called the first principle because it concerns itself with being as it is related to non-being. What is this relation? Obviously one of exclusion or contradiction.

A. The medical profession has ignored this principle in its consideration of the disease influenza. Without a scintilla of proof, direct or indirect, positive or negative, it has taken the existence of influenza for granted. When it asks, "What is influenza?", it implies that the existence of this disease is established. This is unwarranted assumption. This existence has not been established.

B. Under these circumstances the writer denies the existence of the disease influenza. He offers as negative proof the fact that the medical profession has failed to establish this disease. He offers positive proof that this disease does not exist by supplying an alternative condition, which in substance and in category fulfills all the necessary conditions of the unestablished disease influenza. This alternative is nasal sinusitis in epidemic form. An established entity, standardized to Koch's laws.

The first principle of logic is the natural foe of the fallacy known as *ignoratio elenchii*, and of its child the *petitio principii*. It does not allow us to evade the issue (which is the existence or non-existence of the disease influenza) by discussing or attempting to discuss the nature of influenza, or the truth or falsity of the writer's alternative. What it demands is proof that the disease influenza exists. It has received no answer.

2. *The Principle of Identity*.—This second principle is the foundation of all definition and of all demonstration; it is of all definitions the most universal. It is enunciated in the formula: Every being is its own nature, or, Every being is that which has an essence of its own.

Essence is defined in logic as that which makes an object what it is. Essence is also called the quiddity (*quidditas*), because it answers the question, What is this? *Quid est hoc?* In order to discover what is the essence of an object we must ask: If I took away this or that quality, if I reversed it, would its nature simply remain the same as before, save only that this one attribute has disappeared? If it would, then the attribute in question is not the essence. But if there would be a general change in the whole nature, a general disturbance, then such an attribute belongs to the essence and is part of the inner nature.

Let us apply this principle to the disease influenza.

A. What is influenza? What is its essence? What makes it what it is? Let the medical profession answer. That answer is that it does not know. Some few there are who say that it is an acute respiratory disease. This may be true or false. The physician who has seen influenza only in its gastric or nervous forms may doubt it. The fallacy of the definition lies not in its truth or falsity, but in the fact that it is a universal definition, when that which is sought is a particular one. To say that influenza is an acute respiratory disease is to classify it. Classification is not identification. This definition is an obvious *petitio principii*.

It is a fact that the medical profession cannot identify the disease influenza, either in logic or in practice, as the diagnostic errors will testify.

It has established an artificial identity, giving it the name influenza. Any other name would be equally fitting.

B. Under these circumstances the writer maintains that the name influenza is a misnomer, and that the disease known to the medical profession as influenza is actually another disease, namely nasal sinusitis in its epidemic form. To show how he arrived at this conclusion, a word of explanation becomes necessary. The writer first became interested in the disease influenza in the year 1906, and began a study of its literature. He found it, as have others, a kaleidoscopic disease. Nevertheless there was something familiar about it, which he was at a loss to describe. In this contingency he attempted to find one or more constant factors which might prove to be a key to the solution. With this in mind he discovered that all authorities from Weichselbaum to Osler were agreed that purulent nasal sinusitis was constantly found in this disease. Here was a constant factor. What was more important was his discovery that this

was the only admission of constancy in this most variable disease. In influenza, therefore, the sole constant factor was a purulent sinusitis. This was true on the highest authority. Rereading any standard article on influenza, with this fact in mind, the writer found that he was reading the history of a severe, but nevertheless, normal case of nasal sinus infection in epidemic form. He became convinced that the essence of this disease was nasal sinusitis.

Accordingly, in the year 1916, he wrote an article entitled "Epidemic Nasal Sinusitis; Influenza and Grippe Its Misnomers." This article was published in the MEDICAL RECORD, May 27, 1917. In the writer's opinion, therefore, the essence of this disease was a purulent nasal sinusitis.

In the year 1918 the world was visited by a new condition, which puzzled the profession. It was not influenza, but it seemed to be so closely allied to it that it was given the name of Spanish influenza. This was partly to distinguish it from true influenza, partly because it was first noticed in Spain. The situation now was that we had two diseases of which we knew nothing, instead of one.

The writer, however, immediately searched for his constant factor, purulent nasal sinusitis, and found that it was absent. This confirmed him in his opinion that this factor was the essence of influenza. When it was present he had influenza, when it was absent he no longer had influenza, he had something else.

But this something else, Spanish influenza, was a very closely allied condition. If purulent sinusitis was the essence of influenza, another kind of sinusitis might be the essence of Spanish influenza. In other words, was not the difference one of form and not of substance? The writer thought so, and in the *Boston Medical and Surgical Journal*, Nov. 28, 1918, described Spanish influenza as an acute mucous sinusitis, using this formula to express himself: "Acute Mucous Sinusitis is to Acute Suppurative Sinusitis as Spanish Influenza is to Influenza."

The autopsy reports of this epidemic seem to have confirmed this contention. Most of these autopsies were performed during the war and the sinuses were examined macroscopically, and not microscopically. In spite of this the sinuses were found filled, not with pus, but with mucus in percentages varying between 80 and 95 per cent. of the cases. Had the microscope been used it is a fair inference that it would have been 100 per cent. Once again we had a constant factor, the essence of Spanish influenza—a mucous sinusitis. That these facts may take on the semblance of authority the writer quotes the verbal and written opinion of the President of the American Rhinological, Laryngological and Otological Society, based on autopsy reports up to the year 1919, "that the sphenoid sinus would seem to be established as a focus in influenza." In the writer's opinion it is much more than a focus, it is the essence. The surprising thing was that sinusitis was never suspected clinically. Some physicians pointed to the fact that in Spanish influenza the patients were suddenly stricken and collapsed. They did not think it was possible that a nasal sinusitis could do this. The writer had to demonstrate that this

was not only a possibility, but a practical certainty.

In this contingency he thought of the phenolsulphonophthalein test of kidney function. Injecting this dye into the lateral nasal wall, submucously, he was able to recover it in the urine in the average time of 20 minutes. Sealing the ostium and the point of entrance of the needle, he dropped 1 c.c. of the dye into the antrum, and recovered it in the first 24 hours amount of the urine. This shows the approximate rate and potentialities of absorption from the nasal sinuses, and should silence objection to the category of time (*quando*). This experiment is described in the MEDICAL RECORD, Jan. 24, 1920.

With this somewhat long preamble the writer presents his

IDENTIFICATION TABLE.

What is this disease? This disease is its own nature.

- (a) Genus: Acute respiratory disease.
- (b) Species: Epidemic nasal sinusitis.
- (c) Essence: Acute inflammation of the nasal sinuses.

FORMS.

- 1. Mucous.
- 2. Mucopurulent.
- 3. Purulent.
- 4. Fetid.

MISNOMERS.

- 1. Spanish influenza.
- 2. Border-line influenza.
- 3. True influenza.

Tendency to spontaneous recovery.
Tendency to relapse.

(d) Cause: *Bacillus influenzae*.

(e) Category of time (*quando*): Onset, 20 minutes to 24 hours. Phenolsulphonophthalein test. Duration: A few days to six weeks.

(f) Symptoms: Local, general, due to complications.

(g) Standardized to Koch's laws.

This is the identity of the condition which all authorities agree is a constant factor in the disease influenza. The writer maintains that "per se" and "in se" it can account for every symptom attributed to this unestablished and therefore fictitious disease. Nasal sinusitis is his alternative proof.

Before leaving this principle of identity, the writer wishes to emphasize the fact that nasal sinusitis is a distinct organic disease in situ. The nasal sinuses are a portal of entry for infection, but nothing could be more tragic than the belief that this is the whole story. They are much more than a mere portal of entry. They are a base of supply for the multiplication of the invading organisms and the manufacture of their toxins. This is the reason why this disease is so resistant to therapy. The system of therapy which does not recognize this is valueless in fighting this disease.

3. *The Principle of Causation.*—The third principle of logic may be enunciated thus: Every effect has a cause. When we say this we must distinguish between the various kinds of causes. We do not mean the material cause, or that out of which an object is made; nor the formal cause, as the concept in the mind of the architect; nor the final cause, as the end for which an object was made. When we say "every effect has a cause" we mean the actual producing or efficient cause (*causa efficiens*).

An efficient cause must always be an active agent. We must, however, distinguish between an efficient cause in *potentia* and an efficient cause in *actu*. The former is one which possesses the power to do something, but which for certain reasons remains inactive. It is nevertheless a true efficient cause.

An example of a true potential efficient cause would be the bacillus of diphtheria (the germ known to cause the disease of this name), when it is tightly bottled up in a test-tube, where it can do no harm. We know, however, that under certain conditions this potential agent attacks the human

system and becomes immediately an agent in *actu*, causing the patient to become a victim of diphtheria.

Those necessary conditions which transform a potential agent into an active agent are known in logic as *conditiones sine qua non*.

That branch of the science of medicine which makes a study of efficient causes in *potentia* is the department of Bacteriology. Those which treat of efficient causes in *actu* are the departments of Pathology and Clinical Medicine.

In the study of the efficient cause of disease each one of these departments is important, as from each we draw certain facts which we dovetail into a rational conclusion.

Koch had these principles of logic in mind when he enunciated his three laws, which are nothing but a special application of general principles.

Reduced to simple terms Koch's laws may be stated thus:

It is necessary to be able to recognize an efficient agent, and it is equally important to know what that agent is doing. To prove our knowledge we must be able to do likewise with the agent. These three things are absolutely necessary when we wish to establish an efficient cause for a disease. But these are exactly the three things which the medical profession does not know about the disease called influenza, as a consequence of which they have failed to establish it. Whereas with the writer's alternative, nasal sinusitis, these three things have been known for many years.

A. What is the efficient cause of the disease influenza? If we do not know the identity of our effect, and as we have seen, we do not, how can we know its cause? If by some miracle the cause were placed in our hands, how could we correlate it with an effect of whose identity we are ignorant? Is it rational to seek for a cause under these circumstances?

B. The efficient cause of the writer's alternative is an efficient organism or organisms acting under those conditions necessary to bring about a nasal sinusitis. There is no evading the issue that a nasal sinusitis is necessary, unless we are ready to reject all human testimony. It is well known that a nasal sinus may be infected by a variety of organisms. The moment this is admitted the third law of Koch applies to these organisms, and must be considered fulfilled. This has always been accepted, it is not a new idea. By far the most frequent organism to invade and infect a nasal sinus is Pfeiffer's bacillus. So frequent is this invasion that it may be said to possess a selective, specific, infective affinity for the nasal sinuses. It therefore fulfills Koch's third law.

Writing in 1916, the writer said, "that the *Bacillus influenzae* can be taken by mouth, injected subcutaneously or intravenously, with probably some systemic infection, but as long as the nasal sinuses escape, the clinical picture of influenza will be wanting." The United States Navy Department actually did these things in 1918, but did not succeed in infecting their nasal sinuses, and their results were absolutely negative.

On the other hand, by way of comparison with the above quotation, the following is interesting: In the *Medical Clinics of North America*, July, 1920, New York Number, appears an article from the

clinic of Dr. Harlow Brooks, entitled "The Complications and Sequelæ of Influenza and Their Management." In this article Dr. Brooks says, "Russel Cecil, in a personal communication, informs me that in his monkeys experimentally infected with influenza, this early and very persistent involvement of the sinuses is constantly present, even though in his experiments the infection was introduced not by supposedly normal avenues, that is, through the upper air passages, but through intratracheal inoculations." The reader will notice that the *constant factor*, nasal sinusitis, continually comes to the surface. It is certain that the *Bacillus influenzae* may be the sole invading organism in nasal sinusitis, and where it is found in pure state there is no opposite argument.*

But it may be associated with other organisms, in which case it is never going to be possible for the bacteriologist to say dogmatically that the *Bacillus influenzae* is the organism. If it predominates he may say that it is the chief, the others the contributing organisms. As a matter of fact this is the history of these epidemics. There is not a single piece of evidence to support the hypothesis that we have to do with a single invader. On the contrary all the evidence points the other way, namely that the *Bacillus influenzae* is the chief invader, but that other organisms have a very active part.

In fact, as Hajek in his classic, and Lindenthal in the article quoted above, have pointed out, these secondary invaders, as they call them, may be so numerous as to cause the initial *Bacillus influenzae* to be overlooked. This does not prove its absence, they say, but does suggest that bacteriology has not been able to overcome certain difficulties connected with the biology of the *Bacillus influenzae*. Preponderating positive proof favors the latter. However, the important point is that pure or mixed, as in pneumonia, we are confronted with *un fait accompli*, and to wit, a nasal sinusitis. When this has once been established nothing which may happen in the general system should occasion any surprise.

Under these circumstances Pathology transcends Bacteriology. The causative pathology of these epidemics is nasal sinusitis.

4. *Principle of Excluded Middle.*—The fourth and last of these primary laws of thought is the Principle of Excluded Middle. This law, in all its various forms, is but an immediate application of the Principle of Identity, which we have described as the foundation of all demonstration. It may be enunciated thus: Every object of thought is A or not-A; every disease is influenza or not-influenza; or, this disease is influenza or it is not-influenza; or, any two contradictories exhaust the whole field of thought; or, between two contradictories there is no third alternative, no compromise, no middle ground; or, of two contradictories one or the other must be true.

If we analyze the meaning of contradictory, we shall find that it means, in reference to any concept, whatever is not included in it. If we analyze not-A,

we find as the result of the analysis not A. Hence our law will read: The contradictory of any object is that which is not included in that object. This is but a particular application of the general law: All Being is identical with its own essence.

A. Applying this principle to the influenza problem we enunciate it thus: This disease is influenza, or it is not influenza.

The first three principles of logic have not dealt kindly with the attempt to establish the disease influenza, but when we come to this fourth principle we arrive at an impasse.

Not knowing its identity we cannot say that this disease is influenza, and we cannot say that it is not-influenza. Under these circumstances the disease influenza becomes a non-entity. It is analogous to that vacuum which Nature abhors. Influenza becomes a meaningless word, because from the standpoint of Reason it never gets beyond its own spelling. Can we maintain this position? If not, is there any avenue of escape?

Obviously there is a retreat, and that retreat is our second line of defence, the Principle of Identity. If instead of asking, "What is influenza?" we return to the second principle of logic, and ask ourselves "What is this disease?" we shall be on our way to escape the dilemma.

B. The writer enunciates the influenza problem thus: This thing is not A, because it is B; This disease is not influenza, because it is epidemic nasal sinusitis. This is so because this disease in its every manifestation is identical with nasal sinusitis in epidemic form. The nature of nasal sinusitis is such that it may have one or many invading organisms. We cannot change that nature. Why demand the impossible of Bacteriology? By so doing we only cloud the more important issue of Pathology. Nasal sinusitis is a local and a general disease which in substance and in category explains these epidemics *in toto*.

The writer believes, however, that time will prove, that many other diseases, known and unknown, have their causative pathology in the nasal sinuses. He believes that diphtheria, anterior poliomyelitis, the exanthemata, and epidemic cerebrospinal meningitis are diseases which commence as mucous infections of the nasal sinuses. For this reason he believes that the mucous membrane of these cavities should be carefully examined microscopically when the causative organism is unknown. For this reason he believes that the medical problem of to-morrow is the sanitation of the nasal sinuses.

He defends his nomenclature of "Epidemic Nasal Sinusitis" in this disease, because of all the diseases which may be in substance nasal sinusitis, it is the only one which has no single distinctive symptom by which it may be recognized.

Under the head of Categories, diphtheria has its throat symptoms, the exanthemata have their specific skin conditions, anterior poliomyelitis has its paralyses, *et cetera*. These are sufficient to identify these conditions. In substance they may be identical, in category they are different. They are well named, and well identified, even if in some cases the causative or invading organism is still a mystery.

*This well confirmed fact was first established by O. Lindenthal, *Wiener klinische Wochenschrift*, 1897, No. 15.

WHAT CONSTITUTES A FAIR ESTIMATE OF LOSS OF USE OF EYE IN WORKMEN'S COMPENSATION CASES?*

BY WILLIAM MEHL, M.D.,

BUFFALO, N. Y.

THE operation of the Workmen's Compensation laws of the several States of the Union has given rise to many new problems connected with the reporting of diagnostic findings in industrial accident cases. The medical practitioner is called upon not only to supply a scientifically accurate statement of his findings, but to put this in such form that an intelligent layman may understand it clearly and judge therefrom the significance and degree of the impairment sustained.

In eye cases the difficulty of arriving at a final conclusion has been complicated by a regrettable lack of agreement on the part of ophthalmologists as to what should be considered the standard for fixing the percentage of loss of vision sustained by an injured visual organ. The embarrassment of the situation has been felt most keenly by the State officials charged by law with the final adjudgment of compensation cases. In order to bring about a clarifying of controversial points surrounding this particular subject and to arrive, if possible, at a proper basis for estimating degrees or percentages of loss of vision, the State Industrial Commission of New York called a conference of eye specialists which was held at Albany, N. Y., on October 14, 1920, for the full discussion of the subject.

The chief difficulty encountered appears to have been that the findings reported by examining ophthalmologists did not always commend themselves to the injured workmen as well as to the employers, insurance carriers, and the general public. The adjudging officials desire that whatever tests are adopted to prove the findings shall do full justice to the injured claimant for compensation, under the law as it stands, and that these tests shall be simple enough to be applied readily or at least to be verified easily by the official who must decide cases.

In the State of New York, the law makes 123 weeks of compensation the maximum payable for the loss of an eye or the loss of use of an eye. The legislature of 1920 added two important amendments, to wit:

"The loss of eighty per centum of the vision of the eye shall be considered to be equivalent to the loss of the use of the eye, and the loss of binocular vision shall be considered to be equivalent to the loss of one eye."

The Courts which pass upon the Commission's interpretations and applications of the law, in cases of appeal, seem to have taken the ground that the percentage of "loss of use" of an eye shall be based on the percentage of vision remaining, after *advantageous correction* by appropriate lenses. In other words, no allowance shall be made for loss of natural vision so far as this loss can be *advantageously corrected* by lenses. My impression is that the qualification made by the Appellate Division, in one

of the cases on appeal (*Cortina versus Lathrop & Shea Co.*), is not generally understood, as the impression is abroad that compensation shall be allowed only for loss remaining after the highest possible correction. It seems to me, when the Court asked that Commission should be governed in its findings by the question "Whether the vision of eye could be corrected advantageously by use of glasses," the suggestion was that any correction which an injured eye will not tolerate need not be taken into consideration.

Every oculist knows of persons who will not tolerate even a slight lens correction. Besides, there are cases where the correcting lenses would have to be so powerful that they could not possibly be used with any degree of comfort necessary for a wage-earning pursuit. I am aware that the Commission itself is governed by these considerations and will not make allowance for correcting glasses where these cause other disabilities to the injured. The meaning of the phrase "advantageously corrected" appears, however, to have escaped many of us, and I must admit it came to me only quite recently. Here, then, we have one point which the examining oculist will have to consider when reporting his tests, so that the information he may have to give regarding any disadvantages of a correction may be brought to the attention of the Commission.

One other point which court decisions have emphasized is that the law, as it stands, allows only for the loss of an eye and the loss of use of an eye, but not for the loss of *natural value* of an unimpaired eye. The value of an eye that can see without correcting lenses will readily be acknowledged by all. The importance of this value is apparently to receive no consideration as a factor in determining the loss of the use of an eye. It may be that the next legislature can be persuaded to amend the law so as to allow compensation for the loss of value, as well as for only the loss of use of an eye.

Employers of laborers appear to be more or less prejudiced, as a rule, against applicants wearing glasses. To the injured man the change means also that he must shoulder a new burden of expense for the renewal, repair, and replacement of glasses, for periodical re-examination of the eyes, and the like. He is excluded from several kinds of athletic sports. Change from indoor warmth to outdoor cold clouds his glasses and exposes him to new danger. There are many lines of employment in which the wearing of correcting glasses means a distinct economic depreciation for a man's services, and there are not a few occupations from which a man is excluded entirely by reason of it.

It is not unlikely that the Legislature will amend the law still further, in the course of time, so that loss of the *economic value* of an eye may be taken into consideration as well as mere loss of *vision*. However, this is a matter which is probably only remotely related to the present subject of discussion, which is to bring about, if possible, a unification of views as to the most equitable manner for determining the percentage of loss of vision sustained by an injured eye.

*Suggestions submitted to the New York State Industrial Commission at a conference held at Albany, N. Y., on October 14, 1920, for the consideration of this question. Revised for publication.

If I am not mistaken, the New York State Industrial Commission has hitherto based its findings in eye cases more or less, if not altogether, on the Snellen test. Under the law, as amended this

year, vision amounting to 20,100ths by this test would be considered total loss of use of eye, without regard to the degree of remaining peripheral or binocular vision.

I should like to confine myself to a brief examination of the scientific justification of the method of basing loss of use of an eye on the Snellen test exclusively.

We know that vision is a complex act, comprising at least three functions. There is, first, central vision, or visual acuity, the only factor considered in the Snellen test. There is, second, allocation, commonly known as peripheral vision, or field of vision, for which no specific allowance is made in the Snellen test. There is, third, stereoscopic or binocular vision, the loss of which is made loss of use of the injured eye by the New York Compensation Law.

Opinions vary greatly as to what percentage of loss of use of an eye is represented by the findings in a Snellen test. For example, 20/40ths central visual acuity, according to this test, means to the Commission 50 per cent. loss of use of eye; Dr. Frank Alport allows 20 per cent. for the same impairment; Dr. Chapman, 10 per cent.; and Dr. Prince concedes only 5 per cent. A table worked out by the Milwaukee Ophthalmological Society declares 20/40ths to represent 6 per cent. loss of vision, and the table agreed upon by Chicago eye specialists says that 20/40ths is equivalent to 11 per cent. loss of vision. We now have the perplexing condition that a man whose central visual acuity has been reduced to 20/40ths is supposed to have a 50 per cent. eye in New York, an 89 per cent. eye in Illinois, and a 94 per cent. eye in Wisconsin. In other words, a man who is told in New York that the efficiency of his injured eye has been reduced by one-half, learns in Illinois that he really lost only 11 per cent., and in Wisconsin he will be assured that he suffered an impairment of only 6 per cent.

The Milwaukee and Chicago tables are supposed to represent the best judgment of the eye specialists of those two cities. This makes the difference in calculation even more perplexing. We are driven to the conclusion that either one of the two tables is right and the other wrong, or both are wrong.

I have attempted to analyze both tables, and must confess that I am unable to consider either of the two tables to be defensible on scientific grounds. The manner in which these two tables were constructed appears to be purely mechanical. The distance covered by a progressive destruction of vision from 100 per cent. normal to industrial blindness is divided into fractions with arbitrarily fixed denominators.

The Milwaukee table is based upon a 3 per cent. loss of vision for every 10 foot loss of ability to read the letters of the Snellen chart up to 20/350ths, which is considered by that table to be industrial blindness. The Chicago Ophthalmological Society table is based upon a $5\frac{1}{2}$ per cent. loss of vision for every 10 foot loss of ability to read the Snellen chart up to 20/200ths, which is regarded by that body to mean industrial blindness.

Here we have two tables constructed on the same principle, so far as the measurement of central visual acuity is concerned. Both allow a certain

percentage of loss of vision for every 10 foot loss of ability to read letters of Snellen Chart up to a point considered industrial blindness. Despite this fact, the percentage loss of visual acuity varies according to which of the two tables is consulted. This inconsistency is brought about by the fact that the denominators indicating industrial blindness differ in the two cases. The larger the denominator, the greater must be the number of 10 foot stops contained in the table. Thus if the denominator is 100, the distance from normal efficiency to loss of vision can be divided into 10 equal parts of 10 feet each, and if the denominator is 1000 the distance can be divided into 100 equal parts of 10 feet each.

The Milwaukee table uses 350 as the denominator, and there provides for 33 stops of 10 feet each. By dividing 100 per cent. (representing normal vision) by 33, they arrive at 3 per cent. as the percentage of loss of vision for each 10 foot loss of ability to read Snellen letters.

Now if the denominator were increased to 1000—and there is nothing to prevent anyone from doing it—we would acknowledge 1 per cent. as the percentage loss for each 10 foot loss of ability to read Snellen letters.

In the case of Chicago table 200 is the denominator. This 200 is divided by 18, which fixes the number of 10 foot progressions up to 20/200ths. In this way, an allowance of $5\frac{1}{2}$ per cent. loss of vision is made for every 10 foot loss of ability to read Snellen letters. The percentages, it will be seen, are wholly arbitrary and do not in any way represent actual loss of vision in any given case. We can make these percentages what we will by increasing or decreasing the denominator. Such being the case a table based on such a foundation cannot possibly be of any scientific value, it seems to me.

I ought to add here, that in addition to the faulty recording of percentages of visual acuity, as noted above, the Chicago Ophthalmological Society advocates the separation of the three essential factors concerned in the act of vision, allowing 2/5ths for central visual acuity, 2/5ths for field of vision, and 1/5th for stereoscopic vision. I have already conceded the importance of each of these three factors as essential in the act of seeing, which means the usefulness of the eyes. I believe, however, that central vision is relatively the most important of the three factors, especially as regards industrial efficiency. Moreover, it is the factor which is disturbed most frequently in the vast preponderance of cases. Besides, I feel sure every ophthalmologist will concede that, along with loss of central visual acuity, there is, at least in practically all industrial accident cases, a more or less corresponding depreciation of field vision. This loss of field (peripheral) vision usually is not realized by the patient as long as the uninjured eye remains normal and supplies the concealed defect. It would certainly seem reasonable to assume that for every diminution of central visual acuity, however slight, due to the scarring of the cornea or to changes in dioptric media, there is also to be found some decrease of field (peripheral) vision, until a given point is reached where the disappearance of this vision will be conceded by all.

Of all the working tables for fixing the percentage of efficiency for an injured eye, the one prepared by Dr. Snell of Rochester appears to me to be most deserving of serious consideration. It certainly represents more accurately than any table which has come to my notice, the actual loss of central vision, and he is deserving of much credit for this. However, I cannot get myself to accept the table altogether. In Dr. Snell's table twelve steps are involved, each one being credited with 8 per cent., making the total approximately 100 per cent. He starts from 20/20ths and ends at 20/320ths. There we have again an arbitrary denominator, which in this case is 320. By geometric progression he has come nearer to giving adequate allowance for central vision, as by this method the number of progressive steps between the two extremes of normal vision and 20/320ths has been reduced to twelve. But this advantage has been modified to some degree by the adoption of an arbitrary denominator. If he had perchance made his denominator 200, the number of steps would have been still further reduced and a larger percentage of loss of visual acuity would have been recorded for each step.

My personal belief is that the safest standard for determining a percentage of vision is supplied by the Snellen test. By this test 20/40ths means 50 per cent. loss of vision, 20/60ths means 66% per cent. loss, 20/80ths means 75 per cent. loss, and so forth. It is a simple test and has the advantage of being readily understood by laymen. Moreover, the reports furnished to the Commission by examining oculists will have at least an approach to uniformity. Aside from being simple, it has also the merit of being just.

Accidents causing loss of field (peripheral) vision alone are of such extremely rare occurrence that the average injury to the eye should not be minimized by the thought that perhaps the field (peripheral) vision had sustained a less serious loss than the central vision. And as regards binocular vision, I hold that every impairment of central vision affects it in some measure. Furthermore, estimates of the degree of field vision which is supposed to have been lost, would be so much a matter of pure conjecture that I doubt if any two examining oculists would ever agree as to its exact amount.

Taking into consideration, finally, that the New York State law makes loss of binocular vision equivalent to the loss of an eye, there would seem to be no justification for making allowance for binocular vision in cases of ordinary impairment of the central visual acuity.

All this would seem to sustain the proposition that by allowing the figures of a Snellen test to stand for exactly what they are, we have the most equitable method for determining the fraction of loss of vision sustained by an injured eye.

417 FRANKLIN STREET.

Bilateral Orchi-Epididymitis from Serum Injection.—This excessively rare serum accident is reported by Blechmann and Stinssnie. The injection was made for severe diphtheria and the whole syndrome comprised fever, eruption of wheals, arthralgia, albuminuria, and the lesion of the gonads which resolved in about 12 days.—*Le Bulletin Médical*.

THE TRAGEDY OF THE ABDOMINAL INCISION.*

By J. W. KENNEDY, M.D., F.A.C.S.

PHILADELPHIA, PA.

ONE should not write without having lived in the experience of his subject. Papers should have personality and not be composed of bibliography. I grow tired of the fashion of things, they teach nothing. Editors should not take originality of expression from one's paper, by so doing they insert literary brains as a substitute for the life-saving argument of the author's discussion. The strongest clinical teacher I ever knew was the most original and epigrammatic in his expressions. If we had learned and practised one-tenth which is common knowledge of the profession, the death rate in urgent lesions of the abdominal cavity would be less than one-tenth of what it really is. We just cannot catch up to the real privileges of our profession. We will be forced to change the style of our writing and teaching, we get nowhere. The reader is soothed to sleep by the melody of an article. We should be irritated or stimulated to protective action. I constantly see the necessity of giving the medical profession some one definite thought to carry away. It is questionable whether we can forcibly teach symptoms or signs. Had we not better teach a symptom or a sign? I illustrate: the occasion of my writing this paper is that I have been forced of late to resect a large amount of bowel in a great per cent. of cases which have been sent to me for bowel obstruction due to an adhesion from a previous abdominal operation. Now then, if I wrote a paper on bowel obstruction and included that due to adhesions from previous abdominal operations as one of the causes of bowel obstruction, would I impress the medical reader as forcibly as I would if I drove this scar into his mentality as a fertile source of bowel obstruction? The brain remains a useless storehouse of knowledge and is impotent without the ability to call forth a portion of this stock in store. Such ability may be called memory and memory is most stimulated by the vividness of impression by which said act was registered in the brain. A slap in the face is longer remembered than a scolding, etc.

I am not straying from my subject, I am trying to bring out the importance of impression which has much or all to do with men's ability to recall important fact or facts, such as those relative to diagnosis or therapeutics, things they have known but overlooked, with the cost of a life. In other words, we are rarely able to say anything new, but we miserably teach the cardinal points or factors in urgent conditions. The penalty is costly. There is probably not a physician in America but who is perfectly familiar with the fact that an adhesion due to previous abdominal operation is a very fertile source of bowel obstruction and yet in my experience, which has been large, it has been the rarest thing for the physician to have early recognized the bowel obstruction from such source. Further, I at this moment cannot recall a single instance in which I have been compelled to resect a large portion of the bowel but which could have been prevented on account of well marked symp-

*From the clinic of the Joseph Price Hospital.

toms of bowel obstruction which should have been so forcibly impressed at an early hour by the abdominal scar. Therefore, the profession has been in error in just one hundred per cent. of the cases, a very clear indication for stronger teaching on the subject.

So how can I again relate a well known cause of a most serious and fatal condition? Cause, adhesion to the scar; condition, bowel obstruction; indication, instant abdominal surgery. This is the complete story, a thousand years from today will be the same.

Please learn it, the reward is mighty, a life saved. If the reader is a busy man he need not read further, this is my message, this is all the real philosophy there is in it. If you have some patience with me, let us go into the subject just a bit. A negligent profession has made me too familiar with the condition. Why is it we have not been able to impress the profession with the seriousness of this condition? It is for the reason that signs and symptoms are not proportionate to the underlying pathological condition. There is no condition I know in which there is such a disparity between what seems to be a good condition of the patient when measured by pulse and temperature and the real condition which is so often a dying patient. This can be said to be equally true of most internal bowel obstructions, the patient is sick unto death with little external evidence of the same. Experience tells us this, not pulse, not temperature. Experience is the most eloquent of all teachers. Listen to earnest men who are trying to tell the mighty story of experience. Do not live so much by the thermometer and pulse rate, they are only accessories in most of the serious abdominal lesions.

This is a live subject in these days of frequent abdominal operations. As the abdominal incision has increased in length and there has been much exploring of intraabdominal organs by the insertion of entire hand for diagnostic purposes, adhesions constantly follow abdominal surgery. Certain popular teachings of this hour have given us later surgery with more drainage and thus more adhesions. In a large series of abdominal operations in which I did not do the primary operation, ninety-nine per cent. showed adhesions to the scar or lateral to the scar. This morning in the operating room I asked my two assistants who have been associated with the Joseph Price Hospital for fourteen years, in what per cent. did adhesions occur in those outside cases which came to us for re-operation? They both said they did not remember any case in which I had not demonstrated adhesions.

The trouble is men do not look for adhesions and again, it is the teaching not to interfere with adhesions as they are supposed to be sacred to Nature's process of protection. I am prepared to meet such argument with volumes of protest but must not dilate here. The amount of dead bowel in these cases is greater than in the ordinary bowel obstruction from any of the ordinary forms of hernia. This is probably due to the fact that the adhesion causes a twist or rotation of the mesentery of the bowel which would necessarily cut off the circulation to a great amount of bowel. In reviewing the cases which have been my experience, I am within

conservative estimate when I say at least an average of three and one-half feet of small bowel has had to be resected, the extremes being from two to over six feet. So it is a serious operation and done on a patient who has probably been toxic from a partial bowel obstruction for a good length of time and is thus a bad surgical risk. It is not my intention to discuss the symptoms of bowel obstruction from this cause as they are those common to any bowel obstruction, but to impress upon the reader the one and always evident cause, viz., scar of the abdominal incision.

Dozens of times I have cleared the mystery of diagnosis over the telephone by asking the physician: has the patient had a previous abdominal operation? Please ask yourself this, for this is all I have done in a brief discussion about which volumes could be written.

241 NORTH EIGHTEENTH STREET.

NOTES ON THE PROGNOSIS AND TREATMENT OF PNEUMONIA

BY LOUIS FISCHER, M.D.,

NEW YORK.

CONSULTING PHYSICIAN TO THE WILLARD PARKER HOSPITAL.

INFANTILE pneumonia, despite intense bacteriological and clinical study, cannot offer a specific treatment which would apply to a large series of cases. Fatalities occur despite serum treatment even where the specific type of organism is recognized.

The prognosis of a case of pneumonia can best be foretold by studying the leucocyte count. A high leucocyte count, or leucocytosis, denotes good resistance and a good prognosis. When a low leucocyte count, or leucopenia, is encountered then it shows poor resistance and denotes a bad prognosis. So that given a case of pneumonia with a leucocyte count of 14,000, the prognosis is less favorable than in one with a leucocyte count of 20,000.

Toxic symptoms such as drowsiness, restlessness, very high or very low fever, with vomiting, delirium, and twitching, usually denote a severe form of intoxication. It is during this stage that most active treatment is required to insure a good result.

Detoxication can best be accomplished by stimulating the emunctories and eliminating thereby a large quantity of toxins. Aconite supported by fairly large doses of acetate of ammonia, and this followed by a very warm pack will stimulate diaphoresis and rid the system of considerable toxic and effete material. It is very important that such treatment should be supervised by a trained nurse competent to administer caffeine or digitalis should the cardiac condition require the same. Haphazard stimulation with alcohol is unnecessary and harmful. In some cases we irritate the gastric mucosa and thereby lessen the tolerance for food.

When a cardiac stimulant is called for, my choice is adrenalin, but it must be administered in 5, 10, or 20 minim doses until the effect of the same is apparent. Detoxication by diaphoresis should be given at least once in twenty-four hours, depending on the toxic symptoms present and on the activity of the emunctories. The vital organs of the body, such as the bowels and kidneys, especially the latter, should be stimulated to greater activity if a good result is to be achieved. It is important to give large quan-

ties of water by mouth or, if this is not possible, by colonic instillation.

Presuming we have a low leucocyte count, the same can be increased by hypodermic injection of 10 to 20 c.c. of leucocytic extract once in twenty-four hours. If the blood examination is made daily we can easily learn when sufficient of the leucocytic extract has been given. Thus a low leucocyte count of 10,000 to 14,000 if increased within a few days to 20,000 or 25,000 would show a better resistance primarily and also show that the object of giving the leucocyte extract has been attained.

Detoxication can best be accomplished by giving hot tub-baths aided by hot packs. Diaphoresis should be stimulated by giving spirit of milderer and aconite. Stimulation of the kidneys to aid diaphoresis, likewise intestinal stimulation to keep the bowels active and elimination frequent, are valuable aids in detoxication.

Stimulants such as adrenalin, caffeine citrate, or caffeine-sodium benzoate are valuable unless cardiac arrhythmia or irregularity demands digitalis.

Concerning Cold Air.—Fresh air warmed to 65° or even 70° should be advised for susceptible and cyanotic infants. Cyanosis and death have frequently been seen to follow the shock of prolonged exposure to cold air in feeble infants with low resistance. When the vitality is low and the reserve poor, one should remember that chilling of the body does not favor a good circulation and does harm. This does not imply that I am opposing oxygen—far from it. I advise oxygen, but in the form of fresh air without the chill and the depression of cold so fatal in infantile pneumonia.

When caffeine is given the pulse should be watched until it is reduced to 100. Caffeine will steady the heart action as well as digitalis. Besides being indicated in cardiac arrhythmia it is a valuable diuretic.

Hypodermic injections of camphor in oil should be rarely or never administered. While the temporary effect of camphor may be useful the oil used with the camphor leaves a tumor-like residue in the tissues which cannot be removed. These tumors resemble paraffinomas as to their slow development. "When the oil is injected it is deposited between the connective tissue and in the lymph spaces remaining there as an inert foreign body. The localized pressure stimulates a very low grade of temporary inflammation with the gradual production of new connective and fibrous tissue, and a fibroma is gradually produced encapsulating the oil." From the studies of William H. Mook and William C. Wander of St. Louis, made in the service of Dr. Engman, the conclusion is reached that camphor oil should not be used as a stimulant until research shows that it can be made innocuous with an animal fat instead of paraffin.

Dr. John Fordyce of this city states that camphor in oil should not be used because of the danger of producing tumors from the mineral oil. The dangers of emboli from paraffin oil as a vehicle for mercurials has long been known. Knowing the dangers of mineral oil injections we should hesitate to advise them.

The outcome of any case of pneumonia depends on the reserve—naturally the blood strength, and on the amount of nutrition—food and oxygen—properly metabolized. The depression and reduction of the

oxyhemoglobin due to continued fever and loss of sleep are incidents which must be counteracted before normal conditions are reestablished. When very high temperatures are encountered, the loss of fluids from the tissues can be made up by giving a hypodermoclysis of 4 ounces physiological saline solution daily. If for any reason this procedure is objected to, then warm saline colonic irrigations at a temperature of 105° twice daily will supply liquids to the system and indirectly add salt to the circulation.

Concerning Elimination.—This has already been mentioned, but is again emphasized as during an acute intoxication of a febrile nature there is a weakened peristalsis which calls for daily stimulation. A teaspoonful of a saline, the taste of which is disguised with orange-juice, should be given every morning to cleanse the gastrointestinal tract.

Concerning Feeding.—When the body is depleted by fever and the patient is anemic, the indication is to supply nutrition, providing the child can take it. I have tried to add the yolk of raw egg to a cup of broth and sometimes to milk. In some instances steak juice was given as a stimulant with excellent results. Gruels and the carbohydrates were always given when acidosis indicated carbohydrate starvation. The fruit juices are always agreeable because of the palatability and their tendency to quench thirst.

23 WEST SEVENTY-THIRD STREET

A CONCEPT OF X-RAY PATHOLOGY.

XIII. ENTEROPATHY.

(Continued from page 785.)

BY A. J. PACINI, M.D.,

WASHINGTON, D. C.

CHIEF OF LABORATORY AND X-RAY SECTION, HOSPITAL DIVISION,
U. S. PUBLIC HEALTH SERVICE.

Glenard's Disease.—Enteroptosis can be determined by x-ray study, which reveals the exact position of the stomach and intestines in all their parts. The x-rayist is in the position definitely to outline the exact posture of any part of the gastroenteric path. The diagnosis of anatomical enteroptosis is made by inspection of the gastric intestinal x-ray plates. Whether it shares in the etiology of the patient's complaint must be determined by the clinician.

Neoplastic Enteropathies.—Tumors of the intestine may be malignant or benign. Of the malignant tumors, carcinoma, sarcoma, and lymphosarcoma are the most common. Intestinal cancer is nearly always primary. It may be nodular or ulcerative and tends to produce intestinal obstruction. It is unfortunate that the presence of an intestinal cancer is not suspected until the obstruction produced gives rise to obturation symptoms; and by that time, the growth has proceeded to such an extent as to preclude the possibility of surgical intervention with any measure of hopeful recuperation. The x-ray examination may be made after a contrast meal or after a barium clysm. The x-ray pathology is typical and consists of very obvious irregularity in the lumen of the intestine, which irregularity is unchanging and in every case presents identical conformation. It is important that the irregularity or filling-defect in the colon be differentiated from pseudo-filling-defect. Among

the pseudo-filling-defects may be mentioned gas, improperly and insufficiently administered enema, enteric spasm, extrinsic tumors, pressure of bony parts, adhesions, diverticulitis, and scybalous masses. If the x-rayist can make certain that the filling-defect is not an artefact, but is real and persistent, the diagnosis of intestinal cancer is practically established. The minor signs in the diagnosis of intestinal cancer may include enterospasm, and, as the disease progresses more and more, colonic obstruction. It is helpful actually to observe the barium clysmas entering the colonic tract under the fluorescent screen, palpating as the column permeates the colon and examining particularly for spasm and irregularity in the filled contour.

Congenital Enteropathies.—These include congenital malposition, Hirschprung's disease, and Meckel's diverticulum. On the topic of congenital malpositions of the intestines Barker says:

In *situs inversus totalis*, the stomach and intestines occupy a position corresponding to a mirror-picture of the normal; the spleen is in the right, and the liver in the left, hypochondrium; and the thoracic organs are similarly transposed.

In *situs inversus partialis*, the abdominal viscera are transposed, though the thoracic organs are in their normal positions.

Congenital malpositions of the intestine alone occur and may be very important in abdominal diagnosis. The four main forms are: (1) the large intestine lies wholly behind the small intestine, owing to failure of the umbilical loop to rotate—*retroposition*; (2) the large intestine lies in the left side of the abdominal cavity, owing to incomplete rotation of the umbilical loop—*sinistroposition*; (3) the large intestine lies in the right half of the abdomen, owing to partial rotation of the umbilical loop in the wrong direction—*dextroposition*; and (4) there is complete crossing of the small and large intestine, but the position is abnormal, owing to complete rotation of the umbilical loop but in the wrong direction (*situs inversus abdominalis partialis inferior*).

As de Quervain emphasizes, the practically important features are (1) the position of the vermiform process, and (2) the crossing of the small and large intestines. Taking the several malpositions together, the appendix may come to lie in any part of the abdomen.

The matter of the crossing of the small and the large intestine may be important in performing gastro-enterostomy. Ordinarily, the surgeon seeks the uppermost loop of the small bowel where it passes beneath the transverse colon; if the normal crossing has not occurred, it will be necessary to follow the duodenum in order to find the beginning of the jejunum. In sinistroposition of the large intestine, the duodenum passes toward the right kidney, and goes over into the jejunum in the right iliac fossa (de Quervain).

Hirschprung's Disease.—This is a persistent dilatation of the colon characterized by an unusual capacity of the bowel. The congenital condition is met with chiefly in young adults. There are some who would describe an acquired form. Enormous dilatation of the colon, usually accentuated because of meteoric inclusion, can be visualized under fluoroscopic examination without additional preparation; but when a barium enema is introduced the colonic radiopacity is readily observed as an enormously extended structure.

Meckel's Diverticulum.—Meckel's diverticulum or persistency of the omphalomesenteric duct may sometimes be readily visualized by the opaque meal.

Examination of the Gall-Bladder.—X-ray examination of the gall-bladder is useful and may sometimes prove of diagnostic value, particularly with

reference to gall-stones. It has been claimed by some that any gall-bladder is pathological whose outline can be visualized on the x-ray plate; but this sweeping generalization does not seem warranted by the facts.

That there is a relation between the cholesterol metabolism in the human economy and the formation of gallstones would appear established (Pacini). The x-ray pathologist must determine a relation between the presence of gallstones and their radiability. On this score it has been indicated that the radiopacity of a gallstone increases in proportion to its lime contents (Cole). In addition to the lime content, which undoubtedly has much to do in fixing the radiability of biliary calculus, it is also true that the actual density of the stone is as much a determinant in affecting the radiability as is the calcium content (Pacini).

In x-raying the gall-bladder region for the purpose of studying whether or not stones are present every attention must be paid to the minutest details of the technology involved. The preparation of the patient should not include magnesium sulphate purgation for the reason that the gas distention of the intestine practically always incident to Epsom salt purge in many instances will blot out any barely perceptible gallstone radiolucent shadows.* The position of the patient should be postero-anterior. The ray should be directed so that it will not pass through the vertebral column and should be aimed at the gall-bladder in a manner that will make for maximum exclusion of liver. Compression seems preferable. The use of intensifying screens and duplitized films is optional with each investigator, but if used, only fine grained screens should be employed. It is perhaps better to under-expose than to overexpose; but, in studying gallstones, it is important to use a high rather than a low penetration. The reason for using a high penetration (5½ inches or over) rests with the fact that soft rays evolved with low penetrations are rapidly absorbed by soft tissue. Another reason for failure in the x-ray detection of gallstones rests with the fact that the stones are contained sometimes in a bladder filled with thickened bile. In such cases it has been found that the introduction of a duodenal tube into the duodenum and the subsequent injection of one ounce of saturated magnesium sulphate solution acts on the gallbladder in a manner that will make for the expulsion of the bile; and an x-ray examination after the bile has been emptied will sometimes make for visualization of radiolucent gallstone structures not otherwise seen (Pacini).

When shadows are visualized on the plate in the region of the gallbladder it is necessary that they be differentiated from shadows such as renal calculi, pancreatic calculi, calcified mesenteric glands,

*There is recalled a case in which a loop of intestine distended by gas overlaid the iliac pelvis, and by its radiopacity created a circular radiolucency in the bone that could easily be mistaken for a perforative osteomyelitis. It is obvious that if a gas shadow will create an artefact, blotting out bone detail, that a relatively radiolucent gallstone shadow would certainly be entirely obliterated by any overlying gas. In this connection the writer differs in opinion from those who recommend saline purges purposely to inflate the intestine on the presumable basis that gallstones will be made more apparent.

scybala, foreign bodies, and calcified patches in tuberculous kidneys. Stereoscopic x-ray examination of the gallbladder region does not always prove a satisfactory means for the definite assignment of the site of the calculi.

Knox suggests making three exposures in three positions, namely: (1) dorsoventral; (2) ventrodorsal; and (3) lateral or oblique. Gallstone shadows will be larger in the ventrodorsal exposure than in the dorsoventral exposure, which is the opposite from the case of kidney stones, these being larger in the dorsoventral than in the ventrodorsal exposure. And in the lateral view, although these are difficult to obtain with any degree of satisfaction, gallstones will be more ventrally located than renal calculi which are more posteriorly or dorsally located. Among foreign bodies, especial difficulty is sometimes experienced with the case of epithelial papillomata, or warts. These should be examined for previous to undertaking the exposure; and if they are found on the skin of the patient they should be encircled with a lead washer maintained in place through the use of adhesive tape. By this means a wart shadow is soon recognized on the x-ray plate and will not be mistaken for the shadow produced by a gallstone.

There are those who argue that gallstones can be revealed by the plate study in from five to ten per cent. of the cases; and others estimate positive findings in from eighty to ninety per cent. of the cases. There can be no definite expression of the percentage of successful gallstone visualizations, nor should the x-ray evidence in cases of only doubtful shadows be the only criterion in arriving at a positive diagnosis of cholelithiasis. Of course, a negative diagnosis from the x-ray plate is wholly without value.

It is difficult to subscribe to the opinion that any gall-bladder visible on the x-ray plate is pathologic. In particularly thin individuals it may be an easy matter to outline the gall-bladder with the x-ray in the entire absence of gall-bladder abnormality. A valuable sign of gall-bladder trouble may develop from the adhesions that attack the pyloric end of the stomach as the result of inflammatory extension from the gall-bladder. The induced stomach deformity is visualized as a sharp angulation at the pylorus, which angulation persists and is characterized by smooth edges. In the presence of the gastric angulation, revealed by the contrast meal, and of a coexistent gall-bladder shadow which is markedly accentuated, an inference of gall-bladder disease is permissible from the x-ray appearance. For a comprehensive review of the bibliography of the x-ray examination of the gall-bladder reference must be made to the monograph by Knox entitled "Radiography in the Examination of the Liver, Gall Bladder and Bile Ducts."

Pneumoperitoneal Diagnosis.—In this country Doctors Stewart and Stein introduced pneumoperitoneal roentgenography. Their summary of this form of x-ray diagnosis appears in the X-Ray Bulletin of the Hospital Division of the Public Health Service (Volume I, No. 3), and is here reproduced.

The authors were the first to introduce Pneumoperitoneal Roentgen Diagnosis in this country. Since their preliminary report in July, 1919, they have endeavored, by improving the technique, to show distinctly the parenchymatous organs within the abdominal cavity

and their mutual relations, as well as many pathological changes in the same. The procedure has been utilized by them in about one hundred cases. The patients varied in age from 7 to 48 years.

Practically the only accessories required for pneumoperitoneal x-ray examination are: (1) A lumbar puncture needle, (2) rubber tube, (3) rubber bag (such as is used with the gas-oxy-n apparatus for anesthesia), (4) tank for gas.

Formerly they employed oxygen for inflation, but were forced to discontinue its use because of the length of time consumed in absorption. The first step to overcome the objection to oxygen was to deflate the patient after the examination had been made, but on account of the necessity of re-introducing the needle, it was thought best to employ a gas which would be absorbed more readily.

Dr. W. C. Alvarez of San Francisco suggested the use of carbondioxide, but recent experiments by the authors showed that the absorption of this gas was too rapid; all traces of same having disappeared within 15 minutes. At the present time they are using two parts carbon-dioxide and one part oxygen; this mixture disappears within about 30 minutes, thus allowing time enough to make a thorough roentgen examination.

The patient is prepared for the procedure by thorough emptying of the bowels, and, just before the inflation, the bladder should be emptied. We have found it advisable to administer one-quarter grain of morphine before pneumoperitoneum is established.

The lumbar puncture needle is introduced through the abdominal wall into the peritoneal cavity with all aseptic precautions—no local anaesthesia is used. About a half gallon of the gas is then allowed to enter the large sterilized rubber bag which is connected directly to the needle, through a rubber tube, the abdomen is then slowly inflated by gentle pressure on the bag. Thus the gas has an opportunity to warm in the bag before it is introduced into the abdominal cavity. No other warming, filtering or sterilizing apparatus is employed, nor is it necessary to use a manometer; the more complicated the apparatus, the more danger of infection.

In our first experience with oxygen, the patient was troubled with considerable pain in the shoulders; this, however, is now completely controlled by the injection of morphine, the gas being absorbed before the effect of the drug disappears.

One or two cases of puncture of the intestines have been reported. The authors have never had such an experience, but they who were so unfortunate as to enter the intestinal tract with the needle report that there were no ill effects from the accident. It is essential to be sure that the peritoneal cavity be entered, otherwise when the connection is made with the needle and the gas turned on, the tissues become impregnated with the gas and this interferes with clear roentgen detail.

The advantages of pneumoperitoneal roentgenography are that it enables one to see the paranchymatous organs which have not before been visible. We are able to demonstrate the liver, its many pathological changes and deformities; the gall bladder, both normal or pathological, and, in many instances the presence of gallstones; splenic enlargements and the diaphragmatic and subdiaphragmatic spaces clearly outlined. Cysts of the liver, pancreas and ovaries are easily recognized, also malignancies involving the large and small intestines. The female genital organs in their entirety, including tumors of these organs, can also be visualized. Kidney tumors of all characters and peritoneal adhesions are easily outlined. In fact, the possibilities of the method have not yet been exhausted.

Acute abdominal conditions would seem to contraindicate this method nor is it recommended in any case of known valvular heart disease. It has been the authors' experience that a certain type of patients, particularly elderly men who have used alcohol frequently, do not take well to pneumoperitoneum.

At the present stage of development the method should be reserved for the elucidation of diagnostic problems which cannot be "cleared up" by the ordinary roentgenographic methods of diagnosis.

Carman, under the topic of dangers and complications incident to pneumoperitoneal diagnosis, says:

(1) Puncture of the hollow viscera, (2) rupture of abscesses with liberation of infected materials into the peritoneal cavity; (3) fatal embolism by entering a blood vessel with the puncturing needle; (4) respiratory and cardiac disturbances; (5) severe pain in the shoulders due to gas distention; and (6) syncope.

It will be seen by a review of the literature that the method of diagnosis by means of pneumoperitoneum has many possibilities. For instance, Goetze's publications would lead one to believe that practically all organs of the abdomen and their diseases can be demonstrated by pneumoperitoneal roentgen examination. His opinion is doubtless colored by his enthusiasm for he goes so far as to say that examination of the gastrointestinal tract without air filling of the peritoneal cavity is not particularly promising. However, those who have had a vast experience with disease of the gastrointestinal canal well know that lesions of the intestinal tract are best shown by the opaque method.

Both Rautenberg and Goetze state that while they have been able to see the gall-bladder, pericholecystic adhesions, etc., in many instances, they have not been able to demonstrate gallstones consistently by this method. This is what might have been expected since the visualization of gallstones depends on the percentage of calcium in the stones and on the density of the enveloping bile. It is disappointing, however, from a clinical standpoint for any new method by which gallstones might be discovered in a large percentage of cases would have marked a real advance in diagnosis.

Although the kidneys may be clearly shown and many of their diseases are demonstrable by means of pneumoperitoneum it is questionable whether it can be compared for accuracy with the data obtained without air inflation by means of radiography, cystoscopy, differential renal functional test, and ureteropyelography.

The method of pneumoperitoneal roentgen diagnosis unquestionably has much merit, but because of its newness and the likelihood of its being used by the inexperienced it may come into considerable disrepute before its real limitations are learned. As in other x-ray work the difficulty will be in the interpretation of the picture and correlation of all roentgen findings. For this reason the roentgenologist should be chary of reading something into the plate that he does not clearly see.

If the patients for examination are carefully chosen pneumoperitoneum should prove a valuable aid to diagnosis, but it should be resorted to only after all other methods of examination have failed.

Present experience with this form of x-ray investigation is thus far limited; but in the few cases in which it has been used it seems to offer tremendous advantages in the study not alone of the intestines but more particularly of the liver and spleen. Splenomegaly, a topic heretofore unapproachable excepting through the expedient of splenepuncture and percussion has, in a series of 18 cases, been more accurately diagnosed through the use of pneumoperitoneal diagnosis than has heretofore been possible (Pacini).

It seems desirable to add Dr. Le Wald's experience with pneumoperitoneal diagnosis experimentally determined at the Gibbs Memorial X-Ray Laboratory. The conclusions reached by Doctor Le Wald were published in the *American Journal of Roentgenology* for October, 1920, and were as follows:

1. The presence of gas in the peritoneal cavity after the injection of oxygen can be demonstrated as late as eight days after the original injection.

2. A very moderate amount of gas is sufficient for diagnostic purposes. A proportion of about 2 c.c. of gas to 100 grams of body weight appears to answer this requirement.

3. The withdrawal of the gas appears advisable unless a rapidly absorbable gas, such as CO₂, is used.

4. The use of a more readily absorbable gas than oxygen appears desirable.

Note: Since this paper was read an effort has been made to follow the suggestion of Alvarez* and use carbon dioxide alone or a mixture of carbon dioxide and oxygen. The results have demonstrated the very rapid absorption of carbon dioxide, and the retardation by means of mixing carbon dioxide and oxygen in suitable proportions.

Philips, in *Surgery, Gynecology and Obstetrics* for November, 1920, suggests a useful expedient, that of inflating the colon as an aid in roentgen examination. Dr. Philips' communication is so short as to bear reproducing in full.

A patient on the dispensary service of Henry W. Frauenthal, appeared at the clinic suffering from chronic arthritis of the shoulder. In the course of a routine examination, a large tumor, apparently of the left kidney, was noted. It was diagnosed as a hypernephroma, and referred to the x-ray department for further examination.

The roentgenograms resulting from the usual examination of the urinary tract, were unsatisfactory, due to the immense size of the tumor. Its borders blended with the shadows of the spleen, liver, and pelvis, and it was exceedingly difficult to make out the margins of the growth. Oxygen inflation of the peritoneum was thought of but not resorted to because of the reluctance of the patient to stay over in the hospital for a few days, and his absolute refusal to be subjected to any operative procedure no matter how slight.

The following technique was used, a method frequently used in physical examinations, and in roentgen examinations of the bladder, but as far as the author can determine, not described as utilized in roentgen examination of the abdomen proper. The patient was placed on his left side, and a rectal tube inserted into the colon. With a small hand bicycle pump, the colon was slowly and gradually distended to the degree of slight discomfort, when the tube was withdrawn. The roentgen examination was then repeated with very gratifying results. The distended and slightly displaced colon offered a contrasting background, which clearly outlined the tumor, as well as the other solid abdominal viscera.

This method certainly does not offer as universal an application as oxygen inflation of the peritoneum, however its expedience, freedom from dangers and inconveniences, makes the author feel justified in submitting it to the profession at large.

Orndoff has pointed out the value of pneumoperitoneum as an aid in the diagnosis of gynecological conditions. He shows how the pelvic organs, including the uterus, round ligament, oviduct and ovary may be visualized and palpated synchronously. Other conditions in which pneumoperitoneum has proved useful are fibroids, pregnancy, extrauterine pregnancy, ovarian cysts and tumors, peritoneal adhesions with viscera fixation and pyosalpinx. The differential diagnosis of conditions of the rectum, bladder, and uterus has also been greatly facilitated through this expedient.

The new method is deserving of every trial, and great credit should be extended to its introducers for opening a new avenue of approach to x-ray pathologists in their study of the abdominal viscera.

*Alvarez, Walter C. "CO. Instead of O for Injecting the Peritoneal Cavity." *California State Journal of Medicine*, February, 1920.

THE NEWER TECHNIQUE FOR DEEP ROENTGENOTHERAPY.

BY J. THOMPSON STEVENS, M.D.

MONTCLAIR, N. J.

FELLOW OF THE AMERICAN ROENTGEN RAY SOCIETY.

THE newer technique for deep roentgenotherapy is justly attracting more than passing interest from all the world over. Since the method had its origin in Germany it is also called by some the new German technique for deep roentgenotherapy. The only reason for offering this paper at this time is the thought that perhaps those who are having their patients treated with the roentgen rays would enjoy having the facts of this newer technique for deep roentgenotherapy in one short paper.

The old standard technique had for its factors the following: 5 MA of current, 9 in. parallel spark gap, 8 in. focal distance, 6 mm. filter, and an exposure over each area of from 5 to 10 minutes or according to the output of the machine in use. From each area one would cross-fire directly onto the new growth. In most of the cases so treated, I have been able to produce results that were most satisfactory to patient, physician, and myself. But there were a few cases of malignancy that were only made to feel better generally, and perhaps to live a somewhat longer life; also these people did not die the agonizing death that is common in malignancy. Some of these cases I thought ought to have done better, and I believe that in this newer technique we have the means at hand to produce even better results in the future. I have seen many cases do exceedingly well under the older methods but finally become ray-fast, while with the newer technique it is not uncommon to see an inoperable growth of the uterus, for instance, entirely disappear within ten days following the first series of treatments. This is called by the Germans, "the knock-out dose," and I like this term.

The newer technique for deep roentgenotherapy provides for the operation of the tube at a constant voltage equivalent of a 16 in. to 18 in. parallel spark-gap. The filter consists of one millimeter of either zinc or copper. The secondary radiations are now believed to be perhaps equal in value to the primary rays, and so as to increase the secondary radiations the Germans have increased their focal distances to from 50 cm. to 70 cm. and have enlarged their ports-of-entry to 20 cm. x 20 cm. An exposure of three hours is allowed.

It has been shown that when we increase filtration there is a marked change produced in the rays upon the addition of each millimeter of filter. This does not remain so for long, however. When the filter has reached a thickness of four millimeters we find that each millimeter in addition to the four millimeters changes the rays less and less, and that when our filter has reached a thickness of ten millimeters the rays are all practically homogeneous and that further filtration fails to change the radiations. I have followed in the footsteps of Schmidt, Pfahler, and Boggs, increasing my filtration in my deep work for malignancy to ten millimeters of filter material.

We, here in America, have been advised by no less an authority than Dr. W. D. Coolidge not to install the new high power transformer of German manu-

facture, for he doubts very much that the higher voltages obtained from this machine will prove practical. Dr. Coolidge has, however, definitely stated that those who have not as yet been able to raise their voltage to 126,000 must do so in the very near future, otherwise they will not be able to get the best results possible. Dr. Coolidge is at present experimenting with a much more powerful apparatus than the new German machine and will, in the future, let us have the benefit of his experiments. This machine is built to bring a voltage pressure on the tube of 240,000 volts. But, as I have just stated, this is an experimental machine, and Dr. Coolidge himself states that he can see no reason at present for increasing the voltage above 126,000 volts.

Like the Germans, American roentgenotherapists must increase the focal distances and the size of the ports of entry so that the secondary radiations may be increased to their maximum quantities. With our apparatus of the present day the focal distance should be about 30 cm., using ports of entry of at least 20 x 20 cm.

Conclusions.—While my experience with this new technique is limited, like that of other Americans who have tried it, the astounding results obtained with it in the patients who have been subjected to this method have led me to adopt it for all deep roentgenotherapy for malignancy.

The factors for this newer roentgenotherapy, using the present day American machine, equipped with the cross-arm type of rectifying switch (four pairs of cross-arms), are: Pressure on tube of 126,000 volts, 10 millimeters of filter, 30 cm. focal distance, with an exposure of about an hour, according to the value of the machine one is using.

The value of the machine refers to its output. Machines vary considerably, even those of the same make, therefore it is of extreme importance that the operator know the value of the machine he is to use before he attempts this newer technique for deep roentgenotherapy.

Since writing this paper it has been my privilege to examine rather closely some of the new German machines. We find that they are equipped with a spark gap having a disc on one side and a point on the other side of the gap. It is well known that it takes about 40 per cent. less voltage to break down a point and disc gap than it does to break down a point gap. The machines that I have examined are of the coil type with mercury interrupter and a valve tube for rectification of the current to the tube. This gives us rectification of the current to the tube equal to that delivered by a machine rectifying by means of a disc or by two pairs of cross arms, but not equal to the current delivered to the tube by a rectifier using four pairs of cross arms such as are found in the Snook Machine.

The Germans compute their voltages in terms of Peak voltage. It has been the custom in America to compute the voltage in terms of Root Mean Square. To obtain Peak voltage from R. M. S. voltage it is only necessary to multiply the R. M. S. voltage by 1.4. Those who have been using a 9" spark gap have been using Peak voltages of 126,000 while those who have been using the 10" gap have been using Peak voltages of 140,000.

When all these electrical conditions are taken into

consideration one can easily arrive at the conclusion that the best therapeutic machine of American manufacture has a far greater capacity than any machine yet made by the Germans.

The improvements in roentgenotherapy to date made by the Germans are: (1) Increase in size of the ports of entry thereby increasing the secondary radiations; and (2) Increase in focal distance which does eliminate many of the soft rays from reaching the skin and therefore permits us to greatly prolong our exposure over each area. This allows us to deliver a much higher percentage of hard rays to the disease and so produce a much more satisfactory result.

55 PARK STREET.

REPORT OF A CASE OF UROLOGICAL TUBERCULOSIS.*

By M. ZIGLER, M.D.

NEW YORK.

INSTRUCTOR IN GENITOURINARY AND VENEREAL DISEASE, POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; CHIEF CLINIC, GENITOURINARY, LEBANON HOSPITAL, O. P. D.

The patient, Mrs. C. B., aged 29, housewife, born in Russia, presented herself at the Urological Clinic of Lebanon Hospital on October 21, 1916, with the following history: For the past six months, has had pain across her back, in the region of her kidneys, so severe that she was unable to stoop to lift objects from the floor. For the same period has had frequent desire to urinate, urinating as often as every half hour during the day and about five times during the night. The act of urination is associated with pain over the bladder region. This pain is not sharp nor is it radiating but rather a dull, heavy, dragging sensation. Also says that her urine is cloudy. Urine withdrawn from the bladder by a catheter showed a heavy pus cloud, macroscopically. Microscopically, large amount of pus cells, few red blood cells, and tubercle bacilli were found. Abdominal examination showed tenderness on percussion over the left kidney region behind. Abdominal palpation in front, demonstrated a slightly palpable left kidney and considerable tenderness of the same.

Cystoscopic examination on the same day, October 21, 1916, showed a loss of color of the bladder wall, the mucous membrane being of a pale, whitish hue, hemorrhagic areas being scattered throughout the bladder wall, especially in the region of the trigone and near both ureteral orifices. Left ureteral orifice considerably inflamed. I was able to introduce catheters into each ureteral orifice up into the pelvis of each kidney without finding any obstruction. From the right kidney the ureteral catheter delivered perfectly clear urine, from the left, very cloudy urine. Microscopic examination proved that the urine from the right kidney contained no pus or blood. The urine from the left kidney, however, showed many pus cells, a few red blood cells. In neither the right nor the left separated urines could tubercle bacilli be found, although in the combined bladder urine tubercle bacilli were found. Diagnosis from cystoscopic picture: left kidney and bladder tuberculosis. The x-ray picture showed marked enlargement of the left kidney. The patient remained under treatment with creosote and cod-liver oil for about six weeks, with only slight improvement in her symptoms. She then disappeared from observation until April 24, 1917, when she returned stating that she had a left nephrectomy performed about January 1, 1917. On April 24, 1917, she reports that since the operation she has felt much improved. Has no pain on urination. Urinates only twice during the night. Sinus in the left kidney region is not yet healed after four months. Weight at present is 120 lbs. At the time of the operation is was 90 lbs.

*Read on April 21, 1920, before The Bronx County Medical Society under the auspices of Lebanon Hospital.

The patient again disappeared from observation feeling that she was cured. On September 6, 1919, she returned to the clinic, stating that her pains in the bladder region had returned four months ago; that she is now obliged to urinate 20 times during the day and 5 times at night. At present she has pain during the entire act of urination. These attacks come and go, and at times radiate down the right ureter. Weight 140 lbs. Palpation on October 16, 1919, elicited right kidney enlargement. October 23, 1919, urinates every hour during the night. Creosote was again given with only moderate relief of the symptoms.

November 4, 1919, cystoscoped a second time. Ulcerations were found around the right ureteral orifice. The ulceration was so marked that it was impossible to find the opening itself.

November 6, 1919, instilled 5 per cent carbolic solution into the bladder neck.

November 10, 1919, patient returned stating that there was a marked improvement in frequency of urination and diminution of pain. Gave the second carbolic instillation.

November 12, 1919, third carbolic instillation given, with additional improvement in the pain.

November 15, 1919, fourth instillation of carbolic given. During this entire time patient has been taking cod-liver oil and a three-grain pill of creosote three times a day.

November 18, 1919, urinates about every 1 to 1½ hours without pain, 6 or 7 times a night. Relief in pain is more marked than relief in frequency. Received 6 grains creosote pill 3 times a day.

She received several additional carbolic instillations, with no beneficial effects. Since the pain of the instillations began to be out of proportion to the amount of relief obtained, they were discontinued. From that date to this patient has been receiving morphine and belladonna suppositories at night, in addition to the cod-liver oil and creosote internally. Her symptoms are practically just as severe to-day as they were 3½ years ago.

This case is reported not as the unusual but rather to portray the usual picture of urological tuberculosis. Also to show how unsatisfactory at best is the treatment of bladder and kidney tuberculosis, whether medical or surgical, conservative or radical.

Second, this case also shows that some beneficial effects from the symptomatic standpoint may be obtained from carbolic acid, but the results are not quite as wonderful as those Rovsing obtained.

The instillation method is really a modified Rovsing method, the treatment being an instillation of carbolic acid instead of an irrigation.

At best, these cases are the most rebellious and unsatisfactory from the therapeutic standpoint in all of urology.

40 EAST FORTY-FIRST STREET

Sterilization of Prisoners in Europe.—The fact that in several of the United States criminals have been submitted to sterilizing operations does not appear to appeal to European penologists. In Germany especially it has been stated before medical meetings that the moral effects are often deplorable. This propaganda seems strange because the operation is usually reserved for moral degenerates in the first place; nor is it apparent how vasectomy or ligation of the vas can entail any psychophysical change for the worse. The operation of vas ligation according to Steinach has all the value of testicular grafting in the aged (it is, of course, conceivable that the same operation on the young and robust would be a different proposition). It is also stated that during the war many of the greatest men of Germany, including several physicians of eminence, made apologies for the castration of "millions of individuals on the fields of battle." No details are given to explain this remarkable statement and the meaning of the anonymous commentator is not clear. —*Jl Polietnico.*

THE RELATIONSHIP BETWEEN PHYSICO-CHEMICAL BLOOD CONSTITUENTS.

The development of physical and chemical methods which permitted reasonably accurate determination of some of the constituents and characteristics of the blood opened a new field to our laboratory workers. They busied themselves at first with the collection of data concerning the constitution of the blood of both normal persons and those suffering with various diseases. The results thus obtained formed a mass of individual observations which were capable of only a certain limited association with each other. They were valuable chiefly in that they increased our information concerning certain diseases and brought about some improvement in diagnosis and treatment. But conclusions as to the nature of the chemical activity of the body based upon these observations were often later found to be incorrect. Generally speaking there seemed to be but little relationship between the different factors though theoretically some interdependence should exist. This was due to insufficiency of data, imperfections in the methods used and the absence of a broad philosophical review of the whole field.

Now the hydrogen ion concentration (pH) is necessarily a resultant of the balance existing between two or more other factors and as data accumulated and were critically studied some of the governing factors could be recognized. Thus Barcroft was able to show that with known values for any two of the three variables, free oxygen, combined oxygen, and free carbonic acid, the third could be determined. Later Christiansen, Douglas, and Haldane demonstrated the same situation in regard to free and combined carbonic acid and combined oxygen, and Henderson has shown it to be true for free and combined carbonic acid and hydrogen ion concentration. More recently Henderson has extended this work and has been able to trace a close interrelation between the serum chloride concentration and any two of the five variables, free and combined oxygen, free and combined carbonic acid, and hydrogen ion concentration. On this basis he has constructed a nomogram (*Jour. Biol. Chem.*, 1921, xlii, 411) which pictures the relationships graphically. It is composed of six

series of ordinates drawn at different angles. "The relationship between the six variables is such that for a given blood, when values are assigned to any two, the values of the other four are determined and the condition of equilibrium unequivocally defined." Naturally certain reservations are made. It is probable that some of the methods used yield only approximate results. The data were obtained on defibrinated ox and human blood and it is not recorded that disease conditions were represented in the samples studied. But the chart does conform to much that is already known and may be accepted as representing substantially our present information in regard to these variables. It is true that these variables have largely to do with the subject of acidosis and the chart thus has a limited application, but the beginning having been made it is probable that further developments will come more readily. The importance of the realization of the interdependence of various factors is hardly to be overestimated. The different chemical reactions in the body are not completely isolated as if taking place in glass test-tubes; rather they seem to be separated by semipermeable membranes whose varying permeability permits one reaction to exert more or less influence upon others. With proper appreciation of this situation there will develop a better understanding of body chemistry as a whole.

DOES THE CORPUS LUTEUM OF PREGNANCY FORM CHOLESTERINE?

It is of interest to note that Schickelé of the Strasbourg obstetrical clinic, *Gynécologie et Obstétrique*, March, 1921, iii, 2-3, is a holdover from the German faculty of pre-war days, and that the work of which he was in charge as Professor Fehling's first assistant seems to be progressing along the same lines. The latter had to do with numerous phenomena of menstruation and much original work was done in this field. In continuing this work of investigation Gross has been studying the possible relation of the corpus luteum of pregnancy to cholesteroline. The great present-day interest in the substance cholesteroline was inaugurated by Aschoff in Germany and Chauffard in France. While its importance in the economy may have been exaggerated it is true that our exact knowledge of the substance is still in abeyance. The makeup of the molecule is not yet definitely known. The author classes it as a cyclic alcohol, nonsaturated, monovalent, secondary, and having a certain relationship with the terpenes. But while the terpenes are scattered freely throughout the vegetable kingdom, cholesteroline is found in the animal world and is a constituent of all of the animal tissues. Only recently has the technique developed to the point of its successful extraction.

One of the discoveries in regard to cholesteroline is its increase in the blood of the gravida. The curve of increase reaches a maximum in the latter months of pregnancy and after delivery sinks to the normal in 8 or 10 days. Many series of blood examinations make it certain that in pregnancy there

is a hypercholesterinemia. In regard to the place of manufacture of this excess Chauffard first suspected the corpus luteum of gestation. Cholesteroline is found free in the corpuscular elements and both free and bound with fatty acids in the blood serum. When cholesteroline is ingested it is the bound cholesteroline in the serum which shows most of the increase, although the free portion is also increased. The formed elements show no increase.

Cholesteroline is synthesized in the organism from vegetable food containing phytosterines. In the carnivora, the cholesteroline is obtained directly from the animal tissues. When the herbivora are artificially fed with cholesteroline they are unable to eliminate the excess promptly so that it accumulates in the liver, ovaries, adrenals, and elsewhere. But if the carnivorous mammal is made to incorporate an excess of this substance this is quickly expelled by the liver. In castrated females there is a temporary hypercholesterinemia which is soon adjusted, so that in the gravid state the persistence and increase of this substance in the blood cannot be explained by ovarian disuse. The author would explain the phenomenon as follows: The excess formation is clearly for the benefit of the fetus and any excess above fetal needs is probably eliminated by the bowel. The extra amount of cholesteroline must be forthcoming, but the author feels sure that it does not come from the corpus luteum. When the substance is increasing rapidly late in gestation the latter formation has long been in a state of regression and contains but a feeble amount of lipoids as the possible source of cholesteroline. Not in any one organ or set of organs but in the organism as a whole must we look for the source of this increase, which is due to the total metabolism.

THE SOCIAL EVOLUTION OF MEDICINE.

In all countries the practice of medicine is undergoing a change and nowhere more so than in the two great English-speaking countries—America and Great Britain. The trend of modern medicine is preventive and the change is, in fact, a social evolution. This evolution, perhaps, is more obviously apparent in Great Britain than in this country, because in the former a Ministry of Health has been established, the policy of which is naturally more in the direction of prevention than of curative or remedial treatment. The policy of the British Ministry of Health has been ably sketched by its chief medical adviser, Sir George Newman, in his memorandum entitled "An Outline of the Principles of Preventive Medicine."

In a word it might be said that the practice of medicine from being individualistic in a high degree, that is, a patient calling in a medical man when he was sick and only then, has under the altered conditions become a national affair. It is now not so much a question of the doctor bringing the individual back to health as that of maintaining the mass of the people in a satisfactory state of health by preventive means. For example, under this new conception of medical

service, a considerable portion of the British medical profession is engaged in saving infant and child life, in the care of maternity, in school medical service, in the fight against venereal disease and tuberculosis, and so on. Again domestic and industrial hygiene is occupying the attention of all those concerned with the prevention of disease, as it is beginning to be well understood by laymen as well as medical men that, unless people are properly housed and work under favorable sanitary and hygienic conditions they cannot be healthy themselves nor able to breed a healthy race. The problems of home and industrial hygiene are the most important in a campaign waged for the prevention of disease. The evolution which medicine is going through is that it is changing from individualistic to communal in character. Moreover, the principles of practice enunciated and taught by Sir James Mackenzie are preventive in that these principles are based on the early detection of diseases and treatment calculated to prevent their further development.

Large schemes for preventing disease cannot be carried into effect by the individual medical man, maternity schemes and those for saving infant life, for instance, and therefore a part of the profession must be socialized. There will always be plenty of scope for the private practitioner, although his education will have to be conducted on somewhat different lines. While there is no ministry of health in this country, in many respects the advance of preventive medicine is more marked here than in Great Britain. Industrial hygiene has made more progress by far. The Public Health Service teaches and practises preventive medicine on a wide scale and has deserved well of the country by reason of its successful efforts to prevent the dissemination of disease. It would not be too much to say that in the framing and enforcing of measures to prevent disease America is in advance of Great Britain. The main objection urged against the Ministry of Health in Great Britain is that being a department of a government, politics must sway its decisions to some extent, to the disadvantage of the members of the medical profession and the public health. Politically the medical profession is almost powerless; the members thereof working under the ægis of the Ministry of Health are by no means wholly independent, for the ministry may follow a course dictated by the Government from political motives and which may be adverse to the interests of medical men and possibly not in the best interests of national health.

So far as possible politics should be left out of health matters and the medical profession, uniting in non-scientific organizations, such as the various professional guilds now being formed throughout the country after the model of the one in Kings and Queens counties in this State, should be sufficiently powerful to protect itself against political domination arising within or without its ranks. The public health must be safeguarded by scientists and not jeopardized by politicians.

SUDDEN DEATH AT THE OUTSET OF INDUCED ABORTION.

CASES of this nature are not exceptional and sometimes occur at the instant of injecting solutions into the uterus, either when performed by a professed abortionist or by the victim herself. This type of death was named by Brown-Séquard death by inhibition, and is characterized by its calmness and complete absence of death agony, convulsions, etc. The venous blood remains red for a long time in place of turning black, and the postmortem temperature undergoes a rapid decline. According to Caraes (Thèse de Paris, 1920, reviewed in the *Journal de médecine et de chirurgie pratiques* for February 10, 1921, cviii, 3), the determining factor is apparently either puncture of the membranes or detachment of the membranes or placenta by the injection fluid. It is not necessary that there be a lesion of the ovum or uterus, for in certain cases mere dilatation of the cervix by the nozzle has sufficed. The author, however, does not accept the hypothesis of inhibition death in these cases, for thorough study has shown the important part played by air embolism. The chances are, indeed, that every one of these deaths is of this nature. To produce this embolism-death several factors are requisite. The first is the presence of numerous air bubbles in the injection fluid; in the second place, the uterine veins must be exposed by detachment of the placenta or as the result of an actual injury to the uterus; and finally a certain amount of force must have been used in making the injection. Under these conditions air is forced directly into the veins with the inevitable result. Another complicating factor is the caustic or toxic character of some of the injection fluids.

MECHANISM OF MOUNTAIN SICKNESS.

THIS subject is briefly covered by Langlois and Binet in *La Presse Médicale* for February 26, 1921, xxix, 17. Among numerous symptoms, respiratory malaise and asthenia are the most conspicuous at the outset. Later appear precordial anxiety and dyspnea which ceases on repose and is aggravated by the slightest effort. Later with increased aggravation of other symptoms there supervene violent headache, vertigo, confusion of ideas, vomiting, nosebleed, etc., death occurring in an asphyctic crisis. In regard to rationale, Bert and Jourdanet originally made this one of oxygen privation, or anoxemia. Mosso added to anoxemia acapnia or insufficiency of carbon dioxide, a certain amount of the gas being the normal respiratory stimulant. This is borne out by experiment, for whereas pure oxygen cannot give sufficient relief a mixture of O with a percentage of CO₂, which increases with the altitude, does afford relief. In addition there is a mechanical theory to the effect that rarefaction of the air in general causes in time a pulmonary congestion which overworks the right heart. This fact is also emphasized by Mosso. Heger, who is a Belgian, has been at work on the barometric theory since 1873. The main question is "Can rarefied air alone produce mountain sickness by mechanical means?" This and the entire question, in fact, depend on the effects of rarefaction on the blood

picture. High-dwelling birds possess a larger right heart than those on the plains. Altitude causes polyglobulia and increased hemoglobin. The treatment test might show the correctness or reverse of Heger's mechanical theory, for it should consist of remedies to increase the systole—oxygen, venesection, cardiac tonics, etc. The authors ignore Mosso's great work in the domain of aviation in which his theory of acapnia led to the successful use of oxygen-carbon-dioxide mixtures at a certain high level.

ANTIGANGRENOUS SERUM IN GANGRENOUS ANGINA AND PULMONARY GANGRENE.

THE results obtained by Guises from intrabronchial injections of antiseptics into the foci of pulmonary gangrene appear to be equalled by the results of serotherapy, so that a combination of the two resources would seem in theory to be able to control this condition. Houzell and Sevestre publish a case in the *Journal de médecine et de chirurgie pratiques* for March 10, 1921, cviii, 5. The subject was a man of 29 who had been suffering for a month with pulmonary gangrene of unknown origin. There was a violent pain in the side, the expectoration was characteristic, the cough was spasmodic and severe, and fever of the hectic type was present. The general condition was that of the terminal period of a cavitory lesion—the patient being apparently moribund. The serum injected comprised a mixture of the sera of the perfringens and sporogenes in physiological solution, 20 c.c. each in 500, injected intravenously and followed the next day and three days later with a mixture of perfringens, sporogenes, antivibrio, edematiens, and histolyticus sera. The symptoms were slightly aggravated at the moment of injection, but at once began to improve. In three days the temperature was down and one week later all fetor had left the expectoration. The general improvement, however, was still more striking, for in one month's time the subject had gained about 25 pounds. Tixier obtained last fall a similar cure of a case of gangrenous angina. The efficacy of these sera seems remarkable, surpassing, perhaps, that of any other form of serotherapy. The combination of the latter with direct intrabronchial injections seems at first sight to do away with the necessity of surgical intervention for gangrene of the lung.

THE OLD AND NEW CONCEPTIONS OF SCROFULA.

PROFESSOR Marfan delivered a lecture on this subject last January at the Hospital for Sick Children, Paris, an abstract of which appears in the *Journal de médecine de Paris* of March 20, 1921, xl, 8. The older view of scrofula obtained unmodified until toward 1880, its leading manifestations then comprising enlarged lymphnodes, scrofulous facies, blepharitis, keratitis, otorrhea, fungous disease of the joints, etc. The change was brought about by the introduction of bacteriology, which science soon showed that the majority of these lesions were due to the ordinary pyogenic cocci. The enlarged lymphnodes in the neck were often due to the tubercle bacillus and the tracheobronchial glands were invariably of this origin; there was a tuberculous caries

of bone and various tuberculous processes in the skin. But these tuberculous manifestations comprised under the head of scrofula were notably benign, and their presence did not indicate that the subject would be phthisical in after years. On the contrary the presence of these lesions seemed to predicate a certain amount of natural or acquired immunity to the bacillus. But under the age of five years the cuterection is positive and violent. Certain obstinate and obscure dermatoses are regarded by some observers as tuberculides while others look upon them as due to pyogenic cocci. The young scrofulous child is very apt to show the association of a slight degree of rickets and this suggests that diet should play an important role in the treatment.

News of the Week.

Pneumonia Plague in Vladivostok.—A serious outbreak of pneumonic plague at Vladivostok, Siberia, was reported in a cablegram received at the American Red Cross headquarters in Washington recently.

Plans for National Welfare Department.—Brigadier General Charles E. Sawyer, in an address before the Washington Homeopathic Medical Society on May 3, outlined President Harding's public welfare program. The welfare department which is being planned, he stated, would aim to link up education, public health, social science and soldier rehabilitation. Under the proposed plan disabled and ill veterans are promised the aid they are in need of.

Medical Society Invokes Referendum.—The Missouri Medical Society, at a meeting on April 19, adopted resolutions authorizing its Committee on Health and Public Instruction to consider invoking a referendum on Senate bill No. 433, passed by the last Legislature and signed by Governor Hyde, which modifies the law regulating the examination of applicants to practise medicine in Missouri. The bill in question is so constructed that it takes from the Medical Examining Board the authority to define the reputable medical schools, which members of the society assert would result in the licensing of graduates from what are commonly known as "diploma mills."

Louisiana Physicians Protest Against Annual License Fee.—The Louisiana State Medical Society at its annual meeting held in New Orleans April 20, 1921, adopted and forwarded resolutions to the Constitutional Convention urging it to abolish the license fee now exacted by the State for the practice of medicine. The objections to the fee are not on monetary grounds but because the principle is regarded as unjust, and not in keeping with the dignity of the profession.

Hearing on Sheppard-Towner Bill.—At a hearing on the Sheppard-Towner Maternity bill, held in Washington on May 5, emphatic opposition was voiced. Dr. Alfred H. Quessy, representing the physicians of Fitchburg, Mass., asserted that the maternity and infancy aid proposed was superfluous and described the measure as an entering wedge to State or Federal control of the practice of medicine. The bill was attacked by Dr. Charles O'Donovan of Baltimore as a contravention of the general welfare clause of the Constitution and as

an unnecessary additional burden on the taxpayer.

Bonus to French Mothers.—The French Government on April 30 announced that after May 1 a premium would be paid for all children born in France. In the provinces 300 francs, normally about \$60, will be paid for third infants, the scale being gradually increased to 650 francs for the tenth child. In Paris these premiums will be increased 50 per cent. due to the higher cost of living.

Cassel Hospital for Nervous Diseases.—Sir Ernest Cassel of London, who has devoted a large part of his fortune to the endowment of hospitals and educational institutions, has set aside £225,000 to found and endow a sanatorium for nervous diseases. He has purchased a mansion and park at Pensihurst, which will accommodate about sixty patients. It is intended for patients of the educated class who are unable to afford the expense of such special treatment.

Addition to Harlem Eye and Ear Hospital.—A campaign to raise \$50,000 has been launched to finance the construction of an addition to the Harlem Eye and Ear Hospital, New York. The addition is to provide for two children's wards, a special anesthetizing room for tonsil and adenoid cases, and rooms for nurses.

Madame Curie, who arrived in New York on May 11, will be the guest of honor at the annual meeting of the American Association of Social Sciences to be held in New York on May 19, when Vice-President Calvin Coolidge will confer upon her the gold medal of the Society.

New Bill Bans Beer for Medicinal Use.—A bill to amend the prohibition law to prevent physicians from prescribing beer for medicinal purposes was introduced into the House of Representatives by Representative A. J. Volstead on April 25. In addition to specifically prohibiting the use of beer as medicine, the bill makes more strict the regulating the prescription of wine as medicine. Section 2 of the new bill reads as follows: "Only spirituous and vinous liquor may be prescribed for medicinal purposes, and all permits to prescribe and prescriptions for any other liquor shall be void. The Commissioner may limit the number of prescriptions for liquor of any kind that physicians may prescribe and may limit the quantity and alcoholic content of vinous liquor that may be prescribed for use within any specified period."

Influenza Appears in French Camp.—An epidemic of grippe has appeared in the military barracks at Orleans and St. Etienne in a very severe form. In Orleans there are more than one hundred cases in the hospital and ten per cent. of the cases have resulted fatally. In St. Etienne an average of two deaths a day from the disease have been reported for a fortnight. Medical officers believe the disease has been carried by bedbugs in the clothing of recruits.

Child Welfare Exhibit.—The American Red Cross and French welfare societies opened a child welfare exhibit in Roubaix, France, on April 25, under the auspices of the city administration.

Physiatric Institute Opens.—The formal opening of the Physiatric Institute for the investigation and treatment of diabetes and metabolic disorders, located near Morristown, N. J., was formally opened on April 26. The speakers were Dr. Henry

S. Pritchett, president of the Carnegie Foundation; Dr. E. P. Joslin of Boston, Dr. David C. English of New Brunswick, N. J., and Dr. Frederick M. Allen, the director of the Institute.

American Hospital for Havana.—An American hospital, to cost \$300,000, is to be built in Havana through the efforts of the resident and visiting English-speaking people. A bond issue has been planned backed by a trust company which has promised to act as trustee.

New Health Resort and Sanitarium in Florida.—Announcement is made of a projected health resort near Jacksonville, to be called Healthsport. It will have a large hotel with detached bungalows, sanitarium and hospital buildings, club and casino, and churches of several denominations. The president of the association is Dr. C. C. Collins of Jacksonville; secretary, Dr. R. M. Baker, and treasurer, Dr. Theo. G. Craft.

Dr. W. S. Dixon of Metropolis, Ill., is a candidate for the office of Mayor in that city.

Dr. Frank Hunt has been re-elected Mayor of the City of Gibson, Ill.

New Hospital for Mediad, India.—A new hospital building with modern equipment has been presented to the Thoburn Mission Hospital, Mediad, India, by the Mohammedan merchants of the city. Dr. Alexander Corpron of Medford, Ore., is superintendent of the Thoburn Hospital.

Date of State Meeting Changed.—The date of the Missouri State Medical Association, which was to have met in St. Joseph, May 17-18-19, 1921, has been changed to May 24-25-26. The change was made necessary because another convention was scheduled to meet in St. Joseph during the week of May 17.

Medical Society Elections.—THE SOUTH PIEDMONT (VA.) MEDICAL SOCIETY, at its thirty-second meeting held April 19, 1921, elected the following officers for the ensuing year: *President*, Dr. Elisha Barksdale, Lynchburg; *Vice-Presidents*, Dr. E. J. Gregory, Keyesville; Dr. C. L. Bailey, Danville; Dr. R. H. Fuller, Clover; Dr. D. P. Scott, Lynchburg; *Secretary and Treasurer*, Dr. George A. Stover, South Boston.

THE ALABAMA MEDICAL ASSOCIATION, at its meeting held in Montgomery, April 21, 1921, elected the following officers for the ensuing year: *President*, Dr. D. F. Taller, Birmingham; *Vice-Presidents*, Dr. J. A. Howle, Eclectic; Dr. H. S. Ward, Birmingham; Dr. W. R. Jackson, Mobile; *Secretary and Treasurer*, Dr. H. G. Perry, Montgomery.

THE SOUTH CAROLINA MEDICAL SOCIETY at its annual meeting held in Columbia, April 19, elected the following officers for the ensuing year: *President*, Dr. H. L. Shaw, Sumter; *First Vice-President*, Dr. D. M. Crosson, Lexington; *Second Vice-President*, Dr. H. W. Rice, Columbia; *Secretary and Treasurer*, Dr. E. A. Hines, Seneca.

THE LOUISIANA STATE MEDICAL SOCIETY, at its annual meeting held in New Orleans, April 21, elected the following officers for the ensuing year: *President*, Dr. J. E. Knighton, Shreveport; *First Vice-President*, Dr. W. H. Hardy, New Orleans; *Second Vice-President*, Dr. R. Bruce Wallace, Alexandria; *Third Vice-President*, Dr. T. A. Roy, Mansura; *Secretary-Treasurer*, Dr. P. T. Talbot, New Orleans.

THE WEST BALTIMORE MEDICAL ASSOCIATION, at its annual meeting held April 19, 1921, elected the following officers for the ensuing year: *President*, Dr. Arthur Barrett; *First Vice-President*, Dr. W. J. Sullivan; *Second Vice-President*, Dr. F. L. C. Helm; *Treasurer*, Dr. Joseph N. Zierler; *Secretary*, Dr. Gustav Goldman.

THE MCLEAN (ILL.) COUNTY MEDICAL ASSOCIATION, at its regular meeting held in Bloomington, Ill., April 12, elected the following officers for the ensuing year: *President*, Dr. E. L. Brown, Bloomington; *Vice-President*, Dr. William McIntosh, Colfax; *Secretary*, Dr. Ralph Peairs, Normal.

THE WARREN COUNTY (MISS.) MEDICAL SOCIETY, at its annual meeting held in Vicksburg, April 28, elected the following officers for the ensuing year: *President*, Dr. Gus Street; *Vice-President*, Dr. H. C. Denson; *Secretary and Treasurer*, Dr. J. A. K. Birchett, Jr.

THE WINDHAM COUNTY (CONN.) MEDICAL SOCIETY, at its annual meeting held at Putnam, April 26, elected the following officers for the ensuing year: *President*, Dr. E. F. Smith, Willimantic; *Vice-President*, Dr. G. T. LaMarche, Putnam; *Secretary and Treasurer*, Dr. R. C. Paine, Thompson.

THE NORTH CAROLINA STATE HEALTH OFFICERS, at their meeting held in Wilson, April 26, elected the following officers for the ensuing year: *President*, Dr. L. J. Smith, Wilson; *Vice-President*, Dr. A. C. Bulla, Winston-Salem; *Secretary*, Dr. F. M. Register, Raleigh; *Secretary of the State Board of Health*, Dr. W. S. Rankin, Raleigh.

Obituary Notes.—Dr. CORDELIA WILLIAMS of New York City, died at the home of her son in this city on April 29, at the age of eighty-nine years. She was a graduate of the New York Medical College and Hospital for Women in 1878, and a vice-president of that institution up to the time of her death.

Dr. JULIUS C. BIERWIRTH of Brooklyn, N. Y., a graduate of the College of Physicians and Surgeons, New York, in 1885, died suddenly from an attack of heart disease at his summer home at Long Beach, L. I., on May 1, at the age of sixty-four years.

Dr. JOHN A. SHAFMEISTER, health officer of Ossining, N. Y., died there on May 1, at the age of sixty-three years. He was graduated from the New York Homeopathic Medical Society in 1889.

Dr. JOHN KEPKE of Brooklyn, N. Y., a graduate of Bellevue Hospital Medical College in 1890, died on May 1 at the age of sixty years. He was a member of the staff of St. Catherine's Hospital.

Dr. HILLEL SOLOTAROF, a graduate of New York University Medical College in 1891, died at his home in New York City on May 1, at the age of fifty-four years.

Dr. K. M. FERGUSON of Indianapolis, Ind., a graduate of the College of Physicians and Surgeons, Baltimore, died of cerebral hemorrhage on April 24, at the age of fifty-eight years. He was a member of the American Medical Association and assistant superintendent of the Central Hospital for the Insane at Indianapolis.

Dr. ROBERT M. BROWN, chief surgeon at the General Hospital at Saranac Lake, N. Y., died of septic poisoning from a cut on the hand received in the course of an operation on April 30, at the age of

forty-three years. He was graduated from the College of Physicians and Surgeons, New York in 1905 and was a member of the American Medical Association.

Dr. GEORGE HALBERSTADT, chief surgeon for the Philadelphia and Reading Coal and Iron Company, died at his home in Pottsville, Pa., on April 23, at the age of sixty-four years. He graduated from the Department of Medicine of the University of Pennsylvania in 1878. He served in the National Guard and retired as a brigade surgeon.

Dr. A. MCCLINTOCK of Springfield, Ohio, a graduate of the Columbus (Ohio) Medical College in 1887, died following a stroke of apoplexy on April 21, at the age of sixty-seven years.

Dr. JOHN MCLEAN for many years chief surgeon of the Pullman Company, died in St. Mary's Hospital, Centralia, Ill., on April 25 at the age of eighty-four years. He was a graduate of Rush Medical College in 1863, and a Civil War veteran.

Dr. FREDERICK E. WALKER, a graduate of the University of Iowa College of Medicine in 1898, died at his home in Long Beach, Cal., on April 25, at the age of forty-nine years.

Dr. GEORGE A. CARTWRIGHT of McKees Rocks, Pa., a graduate of the University of Pittsburgh Medical College in 1909, died of pneumonia at a local hospital on April 26, at the age of forty-two years.

Dr. CHARLES H. MCILWAINE of Newark, N. J., a graduate of University of Pennsylvania Department of Medicine, in 1877, died April 29.

Dr. JAMES A. MCKEE of Sacramento, Cal., a graduate of Rush Medical College in 1886, died after a lingering illness on April 19, at the age of sixty-seven years.

Correspondence.

OUR LONDON LETTER.

(From Our Own Correspondent)

LONDON, April 18, 1921.

Work of the London Cancer Hospital.—At the annual meeting of the governors of the London Cancer Hospital held recently, the seventieth annual report was presented. This recorded that the new in-patients in 1919 numbered 631 and 810 in 1920, and new out-patients 811 in 1919 and 1,127 last year. The total attendance of out-patients last year was 22,821, compared with 25,728 the previous year, and the daily average number of beds occupied was 82 in 1919, against 93 in 1920. Three new departments had been opened, one for intermediate cases, a dental department, and a medical out-patient department, and during the year the pathological and research departments had been recognized. In the electrical and radiotherapeutic department, under the direction of Dr. Knox, there is provided a substantial quantity of radium, which is constantly in use with excellent results in the treatment of the patients, and the committee are facilitating research with a view to the development of the possibilities of radiotherapeutics.

Effect of the Development of the Thumb on the Eye of Modern Man.—Lieut.-Colonel R. H. Elliott, lecturing on "The Eye in Health" at the Institute

of Hygiene a few days ago, said that reading in bed was considered a vicious habit, but that was because it was so often done with a light behind the shoulder and the eyes turned up. It was the position that did the mischief. If you sit up, he said, and look down at the print and have a good light, there is no reason why reading in bed should be any more harmful than reading at a desk. Long ago, Dr. Elliott said, "the ancestor of man and the higher apes developed the use of the opposing thumb and on this hung the whole future of civilization. The thumb, which could be used in opposition to the fingers, enabled its possessor to pick up and study the objects that lay around him. The objects studied were always held below the level of the eyes, and thus, all through the ages the muscles that depress the eyes have been more called upon than those which raise them. To-day the latter are weaker than the former and are much more liable to tire when the eyes are directed upward. Hence the evil of lying on the back in bed reading a book. If we go to the Royal Academy and look up at the pictures for two or three hours we come away with a headache. Many find the same effect after sitting in the stalls of a theater or a cinema. It would be much better if the picture galleries could be arranged so that we could look down at the pictures from above." On the question of short-sightedness the lecturer said that it was rubbish to say that using the eyes abundantly in an active business life was harmful. He also declared that the majority of shortsightedness begins in influenza, measles or other epidemics; the myopic class are the most intelligent in the community, shortsightedness is hereditary, though no child is born shortsighted. The tendency to acquire it is greatest in the years of growth.

A New Malady.—Recently a considerable number of persons have consulted their medical men with regard to an affection which does not seem to conform to the accepted categories of disease. According to newspaper accounts this malady has puzzled the medical profession with its unaccounted manifestations. While not especially violent in its onset, it raises the temperature for a few days and although not prostrating at first, there is yet a good deal of resulting weakness. It is not in the first instance a skin disease, but is nevertheless characterized by an alarming rash. As the medical correspondent of the *Daily Telegraph* points out, the new ailment breaks most of the rules of a well ordered disease and the only thing that seems certain is that this strange affection represents the efforts of the system to get rid of a poison, but as for the origin of the latter expert opinion is divided. Some aver that it is no more than a variation of the homely measles, or of its imitation, German measles; others confess to witnessing in it the work of a new germ. And, as of course was to be expected, that insidious progenitor of most of the ills to which human flesh is heir has been declared to be at the bottom of this mysterious malady. Granted, that influenza may be the fons *et origo* of such cases, it is practically impossible to place the blame on influenza until the germ of that pernicious disease has been shown to be present. Recent research

in various parts of the world appears to have demonstrated more or less conclusively that influenza is a mixed infection, that is to say, that the disease is not dangerous until Pfeiffer's bacillus has allied itself with other germs rightly notorious for their powers for evil. In the same way, all the ordinary catarrhal troubles which commonly afflict the human race are the outcome of mixed infections, but unlike influenza, of a mild nature. It is likely that the supposed new disease will turn out to be of a catarrhal character. However, it may be due to alimentary toxemia brought about by disturbance of the digestive tract or intestinal stasis. No decision can be arrived at until further and more extended observations have been made.

The Queen and the Royal Free Hospital.—The Queen has announced her intention to visit the Royal Free Hospital, situated in Grey's Inn Road, London, on May 11, 1921. Her Majesty's intention has given great satisfaction to medical women, as the students of the London School of Medicine for Women receive their clinical instruction in the wards of the Royal Free Hospital. The especial object of the Queen's visit is to inaugurate the Unit of Obstetrics and Gynecology which marks an extremely important development in education, the unit on group system which has been introduced on trial in some of the more important London and provincial hospitals. The Unit of Obstetrics and Gynecology is among the first innovations of the kind to be opened in London. Moreover, this hospital is the first to be recognized by the British Treasury as eligible for a grant for a unit in these subjects. The Senate of the University of London appointed recently Dr. A. Louise McIlroy as director of the unit, a tribute to the exceptional ability and organizing powers of Professor McIlroy and a remarkable recognition in itself of the position that women have gained in the medical profession here. With her will be two full-time resident medical officers as assistants. There will be sixty-eight beds under the direction of Professor McIlroy and her assistants, and they will also take charge of the maternity work in the large poor and populous district in which the hospital is located. In addition, there is a branch of the Royal Free Hospital situated near by the main hospital and given by the Duchess of Marlborough. This subsidiary hospital accommodates twenty-six obstetric beds, a few venereal obstetrical cases being included. It is conducted on the lines of a nursing home, being made up of small wards and nicely furnished. It consists of labor, isolation wards and so on. Patients in this department pay for their maintenance according to accommodation. It should be mentioned that research work is to be made a feature of the Royal Free Hospital Unit and with this end in view is being equipped for research work upon antenatal pathology and also upon the physiological aspects of child birth and pregnancy. Special researches will be made into economic questions involved in women's work, and into its influence upon the child and the influence of venereal and other toxic diseases upon pregnancy. The Queen has always taken keen interest in the medical education of women.

Industrial Colonies and Village Settlements for the Consumptive.—In these days when views as to the treatment and care of consumptives are undergoing revision it is both interesting and instructive to read a book dealing with the subject written by men who have made of it a lifelong study and have had practical experience of the working of a system calculated not only to treat and care for those suffering from the disease in all stages, but to render a goodly proportion of them self-supporting. *Industrial Colonies and Village Settlements for the Consumptive* is written by Sir German Woodhead, Professor of Pathology in the University of Cambridge, and Dr. P. C. Varrier-Jones, the honorary medical officer of the Cambridge Tuberculosis Colony at Papworth with a preface by Sir Clifford Allbutt, Requis Professor of Physics in the University of Cambridge. This book gives a description of the manner in which the tuberculosis problem is tackled at Papworth, that is by a combined system. There is a sanatorium, agricultural and industrial colonies and a village settlement. The sanatorium by itself has been a failure, or a partial failure, partly because too much was expected of it and partly because in the great majority of cases it did not cure but turned out men who were unable to hold their own in the rush and tumble of the world, but soon fell again by the wayside and too often the last state of those men was worse than the first. The industrial colonies and village settlements are more or less essential complements to the sanatorium, providing means whereby the consumptive man can be to some extent self-supporting and can live if needs be with his family, without being compelled to encounter the rude shocks of the ordinary workaday world. The book shows that Dr. Varrier-Jones has met with very considerable success in the carrying out of the combined system idea and makes encouraging reading from all points of view.

LETTER FROM GENEVA.

(From Our Own Correspondent.)

GENEVA, April 1, 1921.

Phenylcinchoninate of Allyl.—Some Geneva physicians, among others Prof. M. Roch and Dr. Vallett, have been experimenting clinically with a new Swiss product, namely, phenylcinchoninate of allyl. Starting from the experimental and clinical fact that the substitution of the allyl group for the methyl or ethyl radical has a favorable influence on the therapeutic activity of a drug, researches have been carried out in this direction with phenylcinchoninic acid with the result that an allylic ether of this acid has been produced. This product is composed of yellowish crystals, melting at 30° C., very soluble in ether and fatty oils, slightly soluble in alcohol, and insoluble in water. It is odorless and aromatic in taste. Experimental and clinical researches have shown that this product energetically stimulates the elimination of uric acid; it is likewise endowed with analgesic, antiphlogistic, and antipyretic properties. Given in ordinary doses of twenty-five centigrams four or five times daily, it does not appear to have any irritating action on the

circulatory, respiratory, renal, or digestive tracts.

Clinically, uricemia is quickly diminished by the use of this drug, and it would seem clearly indicated in cases of typical uric acid arthritis. This is the impression derived from its use by Prof. Roch and Dr. Vallett. The therapeutic action of the drug is clear in certain affections of the mucosæ, especially when of an arthritic or gouty nature and in catarrhal inflammation of the respiratory tract.

Swiss Society of Hygiene.—Under this name a new society has recently been founded whose aim is to develop hygiene in Switzerland. In order to better attain this end the society will undertake a general propaganda in order to make the notions of hygiene better understood among the masses. It will suggest the necessary ameliorations, particularly in the domain of social hygiene and working classes. It intends to cooperate in solving the problems relating to the improvement of lodgings and alimentation, the prevention of epidemics and, in a general way, to introduce measures of a prophylactic kind which contribute to assure the health of the public generally and individuals in particular. School hygiene, comprising not only inspection of buildings and school furniture, but the methods of teaching also is one of the problems before the society, and the special aptitude of the scholars as well. The physical development of children and the creation of offices of protection and prevention are also to be considered. Medical inspection of schools and dental care are two important problems to be studied. The hygiene of the worker and the factory, especially of female workers will be thoroughly examined by the new society, as well as the salubrity of cities, towns, and rural districts, while the study of demographic questions, which should give important data as to the future of the population, will not be neglected.

To attain these various ends the society proposes the following means: (1) meetings of the society for the purpose of discussing the questions related to the proposed program of work; (2) the publication of a journal, and (3) the organization of public lectures, courses of instruction and expositions of hygiene and social prophylaxis as well as other manifestations susceptible of contributing toward the aims of the society.

Osteomalacia and the Endocrines.—The attention of pathologists as to the frequency of endocrine changes during the evolution of osteomalacia has not been devoted to this subject for sufficient time to have as yet resulted in obtaining any precise data, but the presence of goiter in senile osteomalacia has been encountered sufficiently often to justify the study of this problem. Dr. Askanazy, professor of pathology at the University of Geneva, has performed within the last few years autopsies in thirty cases of senile osteomalacia, namely, twenty-eight females and two males. In the female cases the presence of goiter or some change in the thyroid gland was noted in seventeen, and it must be remarked that in some autopsies this gland was not examined. But as cases of osteomalacia became more frequent, the indications relating to the state of the thyroid have increased both in number and precision.

For the past few years Professor Askanazy has weighed the thyroid at each autopsy; the two following tables show the average weight of the gland for each decade:

1917		1918	
From—	Number of Grams	From—	Number of Grams
0 to 10 years.....	17	0 to 10 years.....	9
11 to 20 years.....	43	11 to 20 years.....	45
21 to 30 years.....	59	21 to 30 years.....	52
31 to 40 years.....	71	31 to 40 years.....	54
41 to 50 years.....	66	41 to 50 years.....	49
51 to 60 years.....	62	51 to 60 years.....	54
61 to 70 years.....	80	61 to 70 years.....	67
71 to 80 years.....	86	71 to 80 years.....	72
81 to 90 years.....	89	81 to 90 years.....	66
91 to 100 years.....	130	91 to 100 years.....	55

It should be remarked that the decrease observed between the age of forty and fifty years corresponds with the variations of sexual activity, so frequently disordinate, and that after this epoch the size of the thyroid usually increases, perhaps because it plays a part in pathological corruption of the organism. Let it also be recalled that the average weight of the thyroid is given by many observers as between 22 to 25 grams in the adult, but it is also quite true that the average varies according to the country. However that may be, the thyroid tends to increase in size with age, as Askanazy's tables show, and he also states that in old subjects with goiter calcification of the cartilages of the larynx is not always observed.

Diseases of the Circulation in Soldiers.—Some interesting work has been done by Dr. E. Thomas, privatdocent at the University of Geneva, on diseases of the circulatory system of soldiers during the war. He is of the opinion that political circumstances that will follow the war will probably not change the conclusions he has come to. He found that the proportion of organic diseases of the circulatory system did not appear to increase during the war to any extent and those who had preexisting lesions supported both fatigue and emotions very well.

Arteriosclerosis has certainly increased, especially as older and less resistant men were drafted to fill up the ranks. The clinical signs of the process were generally absent, but the frequency of anatomic changes even when very trifling, was very evident. Thomas has found that the number of so-called functional disturbances was especially large at the beginning of hostilities, forced marches, power of the artillery fire, commotions having largely contributed to this, especially in those predisposed. The distinction between an affection *sine materia* and a more or less concealed organic change is very difficult to make. The methods of examination of the functional capacity of the heart are all defective, and Thomas considers that Lian's procedure is the best.

All subjects with organic heart or vascular lesions are to be reformed, while what is known of the nature and origin of functional disturbances should lead to the same decision when tachycardia and high blood pressure persist and when arrhythmia is pronounced. When organic murmurs are not accompanied by important disturbances they are not to be looked upon as a condition for exemption of military service, and when it is clear that functional disturbances have no organic basis, to inform the subject is the worst thing one can do.

THE TONSIL AND ADENOID SITUATION IN NEW YORK CITY.

REPORT BY THE PUBLIC HEALTH COMMITTEE OF THE NEW YORK ACADEMY OF MEDICINE.*

1. *The Problem.*—One of the functions of the Bureau of Child Hygiene of the Department of Health of the City of New York is to give a cursory physical examination to children in public and parochial schools with a view to detecting defects and urging an early correction of the same. Hypertrophied tonsils and adenoids constitute one of the important findings. The accompanying table gives statistics of results of examinations by medical school inspectors of the Department of Health for the 10 years ending 1919.

TABLE I.—RESULTS OF PHYSICAL EXAMINATIONS MADE IN THE SCHOOLS OF NEW YORK CITY BY MEDICAL INSPECTORS OF THE DEPARTMENT OF HEALTH

Year	Physical Examinations Number	Children with Hypertrophied Tonsils and Adenoids Number	Per Cent
1910	266,426	50,012	18.9
1911	230,243	34,639	15.4
1912	237,469	30,021	10.4
1913	330,179	36,958	11.1
1914	308,595	36,153	11.3
1915	278,154	32,356	11.6
1916	276,611	39,731	14.3
1917	328,190	45,947	13.0
1918	347,739	49,475	13.5
1919	348,978	38,151	15.0

From the above table it will be seen that tonsil and adenoid defects are found in from ten to nineteen per cent of the children examined. During the last four years the examiners report these defects in a larger relative proportion than in the four years immediately preceding. Although not all of the cases designated as defective tonsils need surgical treatment, probably a large majority of them do.

Two factors are involved in securing the necessary operative treatment, first, available facilities for performing the operation, and secondly, a willingness on the part of parents to have the operation performed. Through the follow-up work of the Division of Child Hygiene and other agencies, efforts are being made and successfully, to stimulate parents to obtain for their children the proper relief in operative treatment. The complaint, however, is often made that existing facilities are insufficient to meet the demand. Available accommodations have become diminished since greater care is being exercised in connection with tonsil operations and since the dispensaries have practically given up performing them except under hospital conditions. Tonsillotomy is very seldom done and tonsillectomy has come to be regarded as a major operation in connection with which general anaesthesia is usually employed.

2. *Operative Facilities.*—A recent canvass made by the Babies' Welfare Federation brings out the extent to which hospital facilities are available for tonsil and adenoid operations. The total number of operations performed in 1920 is reported as approximately 47,000. This figure is greater by several thousand than the number of children suffering from enlarged tonsils and adenoids, as discovered in the annual school inspection covering each year one-fourth of the school population. There are, of course, the leftovers from former years as well as the pre-school children to be considered in this connection. On the basis of the 1920 census figures there are 455,000 children from 2 to 6 years of age of whom at least 15 per cent. have tonsil and adenoid defects. If one one-fourth of the pre-school age cases should apply for treatment, the annual demand from this source would amount to over fifteen thousand. In that event the annual demand for surgical facilities of the type under consideration would be in excess of the available supply. If systematic follow-up effort, sim-

ilar to that of the Health Department nurses, could be instituted in connection with the pre-school age children, and if one-fourth of both the school and pre-school age children needing treatment should apply, the annual demand for the first few years would be for 55,000 operations. Gradually as the pre-school age children who have had nose and throat defects attended to, enter school, fewer defects of that kind would be found on examination and the demand eventually would resolve itself to the needs of the annual increment of child population. For the time being, however, and for a number of years to come, the annual demand will remain about the same. Hospital authorities should realize this situation and endeavor to meet it. From the estimated potential capacity of the hospitals, as ascertained by the Babies' Welfare Federation, it would seem that the required number of cases can be handled without any great disarrangement of present hospital policy.

As a result of the existing shortage of facilities and the lack of a regulatory system with regard to the distribution of patients, there exists a long waiting list in many of the hospitals. Appointments for operations are made from a week to nine months ahead of time. The Manhattan Eye and Ear Hospital reports from 700 to 800 patients on its waiting list. Bellevue has in the neighborhood of 500. An important fact in this connection is that while some hospitals have long waiting lists, as many as fifteen hospitals in Manhattan, four in Brooklyn and one in the Bronx report no waiting lists at all. Some of these institutions have very limited facilities but a few of them report that they are being able to take care of as many as from twenty to thirty-six cases a week. The fees, higher than the average, charged by some of these institutions may account for patients' seeking treatment elsewhere, although some of the hospitals, like the Gouverneur, charge no fee, and some among those with a constant waiting list charge as much as \$10. It would seem that the established popularity and reputation of certain hospitals are responsible for this uneven distribution of cases. This condition suggests the need of a reference bureau for advice and guidance as to where facilities are available at any given time, such bureau steering patients to the various institutions in order that all available accommodations may be utilized and the average waiting time reduced.

A long waiting period is unsatisfactory from the point of view of the patient as well as of the institution. The patient may not be in a condition to undergo an operation when the appointment falls due, or may fail to appear at the appointed time altogether. At times it is not possible to obtain another patient to fill the vacancy, and for that reason available beds are not utilized. A reference bureau or a district system of admission would obviate this.

A tabulation of the data regarding the number of cases cared for during 1920 in the hospitals of the city shows that the Manhattan Eye and Ear Hospital, Bellevue, Mt. Sinai, and the Brooklyn Eye and Ear are able to take care of a considerable number of patients and a large number of other institutions can accommodate from 20 to 30 tonsil cases weekly. The facilities for tonsil and adenoid work could probably not be increased very materially beyond the stated potential capacity and it may be unwise perhaps to attempt to do so. In order that an unduly large number of beds be not utilized for this work, it is suggested that the hospitals make it a practice to accept larger numbers during the summer when the demands upon the hospitals are not as heavy as at other times, and when the children are free from their school duties.

In view of the demand for facilities, a special institution known as the Tonsil Hospital has been recently established in the city. In addition to private and semi-private patients, the hospital has facilities to receive ten ward patients daily. A fee of \$10 is to be charged, which is, however, remitted when the applicant is really unable to pay.

3. *Pre- and Post-operative Procedures.*—Ever since the Public Health Committee of the New York Academy of Medicine, the Associated Out-Patient Clinics of the City of New York and the State Charities Aid Association, in 1913, took up the matter of procedures in tonsil operations and warned against the performance of such

*Committee: John S. Billings, Chairman; N. D. E. Brill, Samuel A. Brown, Robert J. Carlisle, James B. Clemen, Rufus L. Cole, Charles Loomis Dana, Arthur B. Ducloux, Haven Emerson, Lewis Fox Friedman, Arnold G. Gerster, S. E. Goldwater, John A. Hartwell, Ward A. Holden, L. Emmett Holt, Walter B. James, James Alex. Miller, Charles E. Nammack, Walter L. Niles, Bernard Sachs, Thomas W. Salmon, Charles Hendee Smith, Frederic E. Sondern, M. Allen Starr, Howard C. Taylor, W. Gilman Thompson, Philip Van Ingen, Karl M. Vogel, George B. Wallace, Cassius H. Watson, Herbert B. Wilcox, Linsley R. Williams, E. H. Lewinski-Corwin, Executive Secretary.

operations in dispensaries not properly equipped for the task, the number of institutions undertaking operations without bed facilities for pre and after care of the patients has decreased materially, only a few dispensaries having reported tonsil operations in reply to a recent questionnaire.

In April, 1913, the Section on Laryngology and Rhinology of the New York Academy of Medicine took a census of opinion among its members as to whether tonsillectomies and tonsillotomies ought to be attempted in out-patient clinics. The majority of the members expressed themselves as of the belief that both operations require the facilities of a hospital.

In the same year, on behalf of the State Charities Aid Association, Dr. G. H. Cox examined a number of children who had their tonsils taken out and found that a large number of operations were poorly performed, particularly those that were done without general anesthesia. The conclusions of this study, which were endorsed by the Public Health Committee, were:

That all adenoid and tonsil operations on children should be done under general anesthesia;

That hospitals which undertake these operations should keep the patients for a certain length of time after the operation;

That school physicians and nurses should exercise more care in seeing that only the proper cases for operation be referred to hospitals, and that the children carry out the instruction given.

The Public Health Committee also recommended that private hospitals be requested to cooperate with the Health Department in its efforts to obtain adequate operative treatment for children, that the city compensate private hospitals for this special service when the patients are unable to pay, and that the municipal hospitals be requested to provide similar facilities for the treatment of indigent cases without compensation.

As a result of the pressure brought to bear upon the institutions, conditions have improved considerably. The clinics maintained by the Health Department have been abandoned as being excessively expensive and as involving the department in a therapeutic service which could be provided through other agencies.

A recent canvass by the Babies' Welfare Federation referred to above gives information with regard to certain of the prevailing practices relating to the pre- and postoperative care of tonsil cases in hospitals. In 18 institutions the patient is kept for a day under observation before the operation is performed. In the other institutions the observation period varies from several hours to over-night.

Almost invariably patients are kept for twenty-four hours after the operation although there are some institutions which do not observe this rule. A number of the other institutions keep the children for forty-eight hours after the operation.

In only one of the institutions reporting is no anesthesia given. Almost all of the institutions report that directions for after care are given as to rest in bed, gargle and the return to the clinic for further advice.

The amount of care taken at the various hospitals in ascertaining the condition of the child before operation differs considerably. There is no complete information available with regard to this. Some of the institutions follow wise rules in the conduct of this type of operation. At Mt. Sinai, for instance, the regulations are that no child be admitted for operation whose afternoon temperature exceeds 100°, except when the tonsils are the cause. In such cases, where cardiac and renal lesions may be present, the operation is to be performed by the chief in charge. A complete physical examination, including the examination of the urine and coagulation of the blood, is to be given to each child before the operation. The chief surgeon in charge determines the nature of the operation to be performed and designates the operator. Cases requiring the application of ligatures to stop hemorrhage during the operation remain under observation in the hospital for at least forty-eight hours.

At Bellevue the rules are that every child shall receive a careful examination before admission and that due consideration be given not only to the indications for operating on the tonsils but also to the general physical condition and ability to stand the

operation. Cardiac cases and markedly undernourished children remain in the hospital for several days or a week, if necessary. The desirability of several days' stay in bed following the operation has been demonstrated by studies of the rapidity with which children regain weight after the operation. The loss of weight following the operation stands in inverse ratio to the number of days in bed after the operation, and the regaining of weight is much more rapid in cases which have had a few days' rest.

It is important that the need of careful examination of patients prior to the performance of the operation be impressed on all concerned with these cases in the hospitals; it is also important that post-operative care of a recognized standard should be generally followed.

4. *Summary*.—1. The present annual demand for tonsil and adenoid operations can be estimated as of over 55,000. The existing facilities when fully utilized can probably be made sufficient to meet this demand, but the number of operations performed in 1920 was eight thousand below the estimated demand.

2. There is need for a regulatory system to secure a more uniform distribution of patients among the hospitals and to reduce the excessively long waiting lists in some hospitals.

3. The standards of operative procedure, as well as the care of children, before and after tonsillectomy, differ considerably in the several hospitals. There is a need of stimulating the institutions to an appreciation of the importance of a thorough physical examination of the patients before operation and of provision for adequate care after operation, as well as for more effective methods of instruction as to care to be taken after the patients leave the hospital.

4. A longer period of pre- and post-operative care would reduce the number of cases which can be accommodated in hospitals, and an extension of facilities in certain directions or during certain periods of the year might, therefore, be required.

5. *Recommendations*.—1. That the Babies' Welfare Federation, in view of its function and its close association with the Bureau of Child Hygiene of the Department of Health, be requested to act as a clearing house of information with regard to available facilities for tonsil and adenoid operations in the city; and that the feasibility of districting the city to secure a more even distribution of cases among the hospitals be considered;

2. That the rules governing the care and treatment of tonsil cases before and after operation be standardized in accordance with the best recognized experience;

3. That at each hospital a system be devised whereby the cases most needing the operation should receive preference over less urgent ones, irrespective of whether these cases are able to pay or not;

4. That recognition be made of the large relative expense associated with tonsil and adenoid operations, and that the city be urged to make adequate payments to the hospitals for the care and treatment of cases unable to pay;

5. That the surgeons in hospitals who perform operations as a routine should be compensated for their work; and

6. That, in view of the existing demand, hospitals should allow during the summer months the use of beds outside of the nose and throat wards for tonsil and adenoid cases, provided other demands upon the hospital are not more pressing.

Pulsating Exophthalmus Cured by Ligature of Both Common Carotid Arteries.—The condition resulted from a severe fracture of the skull and was right sided. The common carotid of that side was tied, but no permanent benefit resulted. Greatly annoyed by intracranial noises, the patient consented to the ligation of the opposite common carotid. Thus far the cure has been complete, but there is some slight reason to fear a recurrence. The ligation of the ophthalmic vein for this condition is hardly known in France, but has been done a total of 13 times in the world at large. In most cases, however, one of the carotids was also tied. The thirteen cases have all been successful, eleven having resulted in permanent cure. The route has usually been the palpebral.—*La Presse Médicale*.

4. Impressions Concerning the Etiology of Rickets Among the Italians.—Bessie Talbot Strongman and Ingersoll Bowditch base this contribution on information gleaned from homes by personal observation and with the aid of interpreters. If large families, crowded and dirty living quarters, lack of sunshine, or diet of low energy quotient, were either collectively or individually responsible for rickets, other races would presumably be equally afflicted. But the Hebrews and Poles, for example, in spite of these very things, are remarkably free from rickets. There must be some racial way of life in the case of the city-dwelling American-Italian, to account for the incidence. But little rachitic deformity is found among the Italians of rural and suburban communities compared with the urban population. Early marriages, with a maximum of childbearing period, little attention to prenatal care, puerperium of the ambulatory type, prolonged nursing, added to vitamin-poor diet and generally defective hygienic surroundings are contributory causes to the condition in question. One should learn to advise diets for the children which are known to Italian cooks and palatable to them. This would not be difficult for trained workers. The domestic science course in the schools will be of inestimable value in the next generation. Over the whole, one cannot but feel a subtle process of Americanization—possibly the feministic movement. The writers believe the Italians will adapt themselves to conditions as they exist here, that families will be limited by income and that eventually one will no longer see the rolling, rachitic gait; but the utmost should be done to tide them over until they have adapted themselves.

t. Injuries of the Feet.—U. V. Portmann and F. C. Warnshuis, in an effort to stimulate a better plan of treatment of injuries of the feet based on a better conception of physiological functioning and reaction, draw attention to the following facts: (1) The structure of the foot is complex, and there is a difference in the reaction of the tissues. (2) Injury to an integral part has a large incapacitating influence on the whole member and the individual. (3) The integral part affected must be accurately determined, and roentgenograms made a routine procedure in examination. (4) The site of injury should not be treated exclusively. The whole part and its anatomical and physiological relationship should be considered. (5) Rest in elevation should be instituted at the beginning of treatment. (6) Improper hot bathing is more productive of harm than of bene-

fit. (7) One is always dealing with infected areas. (8) Incisions should be made at sites of election, never on plantar surfaces, and all wounds must be carefully debrided and coapted. (9) Anatomically correct adjustment of footwear merits greater attention and frequently accomplishes the complete eradication of the final results of traumatism.

5. Resistance to Tuberculosis: A Non-Immunologic Chemical Factor Worthy of Consideration.—Corper, Gauss and Rensch hold that humoral antibodies have failed to explain resistance to tuberculosis; the lymphocyte as the important factor is rapidly being discarded; allergic phenomena require further elucidation, and the phagocytic action of the wandering endothelial cell is recognized as important. But both humoral and cellular mechanisms of resistance leave much to be explained. Weber's (1889) empiric reasoning that the deficiency of carbon dioxide in the body favors tuberculosis, while an accumulation retards it, seems to be highly significant and appears to be substantiated by the experimental work thus far conducted by the writers. Three per cent. carbon dioxide inhibits the growth of tubercle bacilli in the test tube, and 15 per cent. is tuberculocidal. Cultures of tubercle bacilli buried in the tissues of animals and permitted to acquire the carbon dioxide concentration of the body are definitely inhibited in their growth, while other cultures similarly buried, except that ingress of atmospheric air is permitted, show no inhibition. It appears that carbon dioxide may play a significant rôle in the resistance to tuberculosis. This reopens the consideration of the influence of fatigue exhaustion, exposure, metabolic diseases, etc., as probable etiologic factors in the causation of tuberculosis in view of their ability to alter the carbon dioxide content of the body.

9. Auricular Flutter and Fibrillation in Pregnancy.—Clarence P. Thomas found no report of cardiac arrhythmias in pregnancy. The case which he reports illustrates the possibilities of treatment in such cases when they occur or are discovered late in pregnancy. It shows the advantages of a prompt and accurate diagnosis followed by digitalis therapy. He does not recommend similar treatment for all such cases, since the handling of these patients must depend upon the advisability of allowing the pregnancy to go to term, considered, of course, in conjunction with the purely obstetric aspects of the case.

5. A Fatal Case of Colic Infantilis, with Comments on the Morbid Anatomy.—Reginald Miller gives the details of a fatal case of colic infantilis in which postmortem examination failed to show any chronic changes in the pancreas, liver, intestine, or elsewhere to account for the prolonged failure in fat-digestion. The only autopsies hitherto recorded in cases of at all a similar nature have been discussed in detail and it has been argued that the intestinal changes found in them do not prove that the excessive fat-loss in colic disease is due to an enteritis. Other reasons against the view that colic disease is essentially an enteritis have been given. From these arguments it is concluded that colic disease is independent of organic changes and thus must be due to a digestive fault (probably a defective action of the bile on fat-absorption).

1. A Clinical Lecture on the Orthopedic Treatment of Poliomyelitis.—H. A. T. Fairbanks follows the customary division of poliomyelitis, for purposes of treatment, into the early acute stage, which lasts while there is pain and tenderness in the muscles; the second, or convalescent stage, during which the recovery of power is taking place—it lasts to the end of the first and sometimes the end of the second year; and the third stage, which begins after the lapse of two years. Until the third stage all reconstructive surgery is delayed. During the first stage the first essential of treatment is rest, both for the spinal cord and for the affected muscles. Steps should be taken to provide rest for all the affected muscles, and this involves rest for all their opponents as well, should these not be paralyzed. Splints or other fixation apparatus should be applied at the earliest possible moment, the limbs being fixed in the neutral position. Without fixation deformities are certain to occur. As regards the correction of deformity at this stage, it will be found easy to stretch contracted muscles. When the muscles are still tender, except in cases where this tenderness is unduly prolonged, very gentle persuasive manipulations with fixation on a splint which is slightly altered in shape each day will achieve correction of the deformity. The stretching is painful, and must be done with the greatest gentleness; if the foot is fixed in the position which is the best possible one day, it will usually be found possible to improve this slightly the next. Massage should be carried out with the greatest gentleness, and one must be guided by its effects in each case. Electricity is useless in this stage. The writer sounds a note of caution with regard to the spinal muscles. He urges the advisability of raising the child to a sitting position slowly and gradually by means of a bed rest and pillows. The spinal muscles should be massaged, and any paresis and tendency to curvature looked for. In a case well treated throughout, a muscle which is absolutely paralyzed after twelve months must be regarded as hopeless. During the second year further recovery may take place in all those which have to some extent recovered, but a muscle which remains paralyzed for many months before showing any return of power will never be of much use to the patient. The treatment during the second stage comprises keeping the part warm, relaxation of the paralyzed or weak muscles, massage and reeducation of muscles, to which must be added correction of deformity, if such has been allowed to occur. Without adequate support recovery is bound to be far from complete, and will be coupled with deformity. Splints are more efficient correctors of a tendency to deformity than any walking apparatus. The avoidance of overstretching a paralyzed muscle, particularly in the early stages of its recovery, is essential for good recovery. Whether this prevention of overstretching should be carried to the extent of absolute relaxation—or, in other words, whether the neutral position is sufficient—or whether the limb should be put in a position to relax the paralyzed muscles at the expense of their unparalyzed opponents, is still an open question. In the case of the leg, bandages or straps used to hold the limb in the splint should encircle the foot and ankle and, at the most, the lower third of the leg; the muscles themselves should be free of all pressure. The splints must be left on day and night, and removed only for washing, massage, etc., when the position of the limb should be maintained by the hand of the attendant so long as any marked degree of weakness persists. As soon as recovery has progressed sufficiently walking should be encouraged, suitable apparatus being employed. Reeducation means nothing more than exercise carried out with a minute regard for the development of individual muscles. Operative treatment during the second stage should be confined to the correction of deformities. The operative procedures are practically limited to tenotomies, fasciotomies, wrenching, and tendon lengthening. Having corrected deformities, the parts should be retained in over-corrected position so as to relax as much as possible the weak muscles and stretch the strong, while re-

education, massage, etc., are carried on vigorously. In the third stage various problems are presented, when further recovery of muscle power is impossible. Tendon transplantation and arthropodesis are discussed somewhat in detail in this connection.

3. Cancer Infection.—Albert J. Ochsner reviews this question, and urges the importance of taking every precaution against cancer infection, notwithstanding the fact that its infectiousness has not been proved. Wise precaution can do no harm, while it may do an endless amount of good, because, in case the disease is due to infection, every additional case is a menace to others. He considers the most convincing argument of the infectiousness of cancer to be found in the studies of Smith, who claims that cancer in plants is due to a microorganism which he has been able to isolate and cultivate, and which produces cancer when inoculated upon healthy plants. In human cancer further studies are needed, and the writer expresses the hope that these will be continued vigorously and that in the meantime healthy persons be not exposed unnecessarily to cancer infection. The fact that many competent observers have been unable to prove to the satisfaction of others that they have found the microorganism causing cancer must not be construed to prove that such an organism does not exist, because precisely the same failures were experienced before the tubercle bacillus, the bacillus of leprosy, the spirochete of syphilis, the plasmodium of malaria, and many others were finally discovered. Clinically all these diseases were infectious, and it was only a matter of patient labor to find the living cause.

7. Laryngeal Function in Thyroid Cases.—Edward Starr Judd was prompted to make the study on which this paper is based by a small group of cases of bilateral abductor paralysis (twelve cases). The voices of these patients are usually normal or may be very slightly impaired; the principal disturbance is in respiration. In approximately 25,000 thyroidectomies Judd and his associates have had nine patients with this trouble, and three others were observed who were operated on elsewhere. Temporary disturbance in the voice and respiration is not uncommon following thyroidectomy. The factors involved are: (1) A change in the position of the muscles and cartilages because of the shifting of a misplaced larynx back into its normal position; (2) edema of the tissues; (3) a true myositis; (4) trauma to the recurrent laryngeal nerve; (5) prolonged interference with function. Under the last category, bilateral abductor paralysis, cases are extremely rare. They are so serious, however, that they deserve a great deal of consideration. The condition progresses until there is considerable difficulty in breathing, especially on exertion, and from then changes are slow. In none of the writer's patients has phonation been affected except from dyspnea. After a long time the tendency seems to be toward improvement.

Tracheotomy may be necessary because of the small margin of safety, although so far as it has been possible to determine, there is no danger of acute suffocation. The cords are held in adduction by the contraction of the adductor muscles, and it is probable that these muscles would relax enough to allow the entrance of air in case of any suboxidation. For the treatment of these cases other than tracheotomy he suggests the advisability of dissecting the recurrent laryngeal nerves from the scar tissue, in the hope that by freeing them the pressure of the contracting scar might be relieved and enable the nerve to functionate normally. The performance of a plastic operation on one vocal cord in order to give more breathing space has been considered, but has not been attempted because of the fear of interfering with the voice. It may be said in conclusion that (1) the functional results following thyroidectomy, both as concerns phonation and respiration, are extremely good; (2) the disturbance which sometimes follows immediately after the operation is temporary, and normal function will be restored in from a few days to a few weeks; and (3) there is a very small group of patients who, following thyroidectomy, have a bilateral adductor disturbance which is slow in onset but is very persistent. The cause of the condition has not been worked out, but it is believed that it may be due to the contraction of a scar, to a peculiar type of trauma to the nerve, or to some form of toxemia.

15. Röntgenographic Studies of Bronchiectasis and Lung Abscess After Direct Injection of Bismuth Mixture Through the Bronchoscope.—Henry L. Lynch and William H. Stewart summarize their experience and observation on this subject as follows: (1) Bismuth mixtures can be injected into the bronchi and lungs of a living patient without danger. (2) The injection of an opaque substance into the lung of the living patient will open an enormous field of usefulness in the study of cough, the expulsion of substances from the lung, and lung drainage. It will also aid in localizing bronchial strictures in the same manner as in the esophagus. Furthermore, it will be of the greatest aid to the thoracic surgeon by mapping out the abscess cavity in the respective lobe of the lung. (3) A definite lung abscess cavity is seldom seen bronchoscopically. Pus is usually seen coming from a branch bronchus, although the abscess may be well around the corner, and not in that portion of the lung from which the pus is oozing. An injection of bismuth mixture or some other opaque mixture will "clear up" this error. (4) Bismuth when it enters the abscess cavity is recognized by its metallic luster, whereas, when it is in the lobular lung structure, it is discerned as a dull, opaque area. Pus diffuses and soaks the lobular structure in a manner similar to bismuth; this often makes the involved area appear many times larger than it really is. (5) The bismuth mixture injected in these patients was 8 c.c. of bismuth subcarbonate in pure olive oil (1-2). The mixture is rendered sterile by boiling before injection. (6) The injection should be made slowly and not with a "squirt," or else the röntgenographic observations may be spoiled by bismuth soaking the lung structure surrounding the diseased area. (7) It seems from these preliminary studies that cough and action of cilia are not the only means of expelling secretions. (8) While bismuth mixtures were originally injected for the purpose of lung mapping in cases of lung abscess cavities, they seem to have been of therapeutic benefit to the five patients upon whom they were tried. So far the procedure has done no harm. (9) While the fluoroscopic examination is important, stereoröntgenographic examination is the best means of localizing the cavitations. (10) Experience has shown that the Röntgen examination should be made almost immediately after the removal of the bronchoscope, otherwise the patient, in a fit of coughing, will remove much of the bismuth from the involved lung.

4. Chronic Leukorrhea. Carl Habich.

1. The Use of Mercurochrome in Ophthalmic Therapy, with Report of Cases.—M. Ravadin finds in mercurochrome-220 a germicide possessing the triad of virtues sought in the ideal germicide—high germicidal power, low toxicity, and slight irritating action. A 1 per cent. solution dropped into the conjunctival sac gives no evidence of irritation, while 2 to 5 per cent. solutions are followed by smarting sensations lasting no longer than a minute. A 1 per cent. solution is as potent a germicide as a 25 per cent. solution of argyrol. It seems to act equally as well on all bacterial flora of the conjunctiva. Mercurochrome is also valuable in all types of corneal ulcer. In ulcer serpens, when used in conjunction with pasteurization, it seems to inhibit the growth of the pneumococci, cleanses the ulcer of microorganisms, and enhances the healing of the ulcerated area.

La Presse Médicale.

February 12, 1921, xxix, 13.

Hemoclastic Crisis from Ingestion of Sugar by the Diabetic.—Widal, Abrami, and Iancovescu begin with the statement that when a healthy subject ingests sugar in any amount, however large, the blood never shows a hemoclastic crisis. But if a diabetic takes more than 20 grams of glucose he will show a hemoclastic crisis in 85 per cent. of cases. Some of the negative subjects will show the crisis if the dose is increased to a certain extent and it is not mentioned that any diabetic is universally refractory. To make the test have the patient begin a short fast on a given evening and then on the next day make a blood test before the special procedure in order to determine the normal leucocytosis. The sugar is then swallowed in water solution (200 c.cm. water), and every twenty minutes for an hour and a half tests for leucocytosis are maintained. The first test made twenty minutes after the ingestion will show leucopenia such as is characteristic of the hemoclastic crisis. By comparison with the fasting leucocytosis it may often be seen that the mere taking of 20 grams of sugar will cut the white blood cell count in half. In other cases this is seen in but a slight degree. If leucopenia were the only phenomenon produced we might not speak of a blood crisis, but other behavior accompanies the fall in the white cell count, such as lowered blood tension and hyper-coagulability; but for practical purposes the cell count suffices. The reaction is not limited to glucose, for saccharose, lactose, and levulose also cause it. The discovery is regarded by the authors as highly important in a biological sense, although in the clinic its importance is not yet fixed.

La Presse Médicale.

February 16, 1921, xxix, 14.

Cesarean Section for Penetrating Wounds of the Gravid Uterus.—Constantinesco reports a case of this very rare accident. The cesarean operation for the relief of such cases is still more infrequent because the wound may not be serious enough to merit the intervention. In the author's case the woman was nearly at term, when she was gored. She was at once carried to the nearest hospital. The child was living and the head was presenting with occiput to the left acetabulum. The waters had ruptured, but there was no sign of labor. The wound ran from the left flank toward the umbilicus, and in it could be seen the pulsating cord. Neither hemorrhage nor pain was marked but there had been considerable internal bleeding. The wound was enlarged and clots scooped out, while all lacerated tissues were excised. The fetus was extracted through the wound and was in good shape when handed to the attendant. After slight delay the placenta was readily extracted. The uterus, allowed to retract on itself, ceased to bleed. It was packed with gauze, which was allowed to project into the vagina. The uterus and abdomen were then sutured, gauze being used also for external drainage. The double use of gauze externally and internally was maintained for many days. The abdominal gauze was filled with pus when the dressings were first changed at the sixth day, but there were no evidences of infection. Convalescence lasted 45 days.

Book Reviews.

STUDIES IN NEUROLOGY. By HENRY HEAD, M.D., F.R.S. In Conjunction with W. H. R. Rivers, M.D., F.R.S., Gordon Holmes, M.D., C.M.G., James Sherrin, F.R.C.S., Theodore Thompson, M.D., George Riddoch, M.D. In two volumes. New York: Oxford University Press, American Branch, 1920.

THESE two volumes of the Oxford Medical Publications consist mainly of papers which have appeared in *Brain* between the years 1905 and 1918, inclusive. Volume I, in two parts, deals with methods of examination, and the peripheral nervous system. Under the latter is given, in eleven chapters, an interesting "human experiment in nerve division," with general theoretical conclusions. Volume II, also in two parts, includes the grouping of afferent impulses within the spinal cord; the automatic bladder, excessive sweating, and some other reflex conditions in gross injuries of the spinal cord; sensory disturbances from cerebral lesions; sensation and the cerebral cortex; an epilogue; an appendix, with criticisms of the authors' work; a bibliography, and an index for the two volumes. There are 182 illustrations. Readers of *Brain* will find this work familiar, since it has been deemed expedient to make no material change in the arrangement of the articles as they appeared in that periodical. Each deals with a definite theme and is concerned with some aspect of the functions of the nervous system. In the course of the work recounted in these volumes an effort was made to trace the physiological processes produced by various stimuli from their origin at the periphery of the nervous system to the moment when they excite sensation. It has been shown that they are subjected to far-reaching changes during their passage through this zone of physiological activity, which in many cases give the key to the evolution of function in the nervous system. The observations recorded have both a practical and a theoretical bearing, for example, the discovery of the nature of protopathic sensibility and of the significance of the mass-reflex are some aid to clinical diagnosis. The wider theoretical bearing of the work is discussed in the epilogue. Like others of the Oxford series, these volumes are excellently well printed on good paper. Whether one does or does not agree with all the findings, the work of the contributors brought together in this form, must prove a valuable addition to modern neurological literature.

LOCAL SHOCK AND THE SHOCKLESS OPERATION THROUGH ANOCI-ASSOCIATION. By GEORGE W. CRILE, M.D., Professor of Surgery, School of Medicine, Western Reserve University; Visiting Surgeon to the Lakeside Hospital, Cleveland; and WILLIAM E. LOWER, M.D., Associate Professor of Genito-Urinary Surgery, School of Medicine, Western Reserve University; Associate Surgeon to the Lakeside Hospital, Cleveland; Surgical Director, Mount Sinai Hospital, Cleveland. Second Edition of Anoci-Association, Thoroughly Revised and Rewritten. Edited by ARY F. ROWLAND, B.S. Philadelphia and London: W. B. Saunders Co., 1920.

ACCUMULATING experience in civilian and war work has added so much corroborative evidence of the soundness of the fundamental principles of anoci-association and of its practical application, that Crile and Lower have rewritten and enlarged their former volume. As in the first edition, their purpose is to present as concisely as possible the principles upon which the doctrine of anoci-association is based and their practical application. To this end they have omitted any discussion of the various other theories of shock and proceed at once to elucidate the evolution of their theory of shock (which they call the kinetic theory) and establish the identity of shock with cell exhaustion, since they find the histological changes in shock and exhaustion from any cause are identical. They state that surgical shock may be produced by many factors—emotional, such as fear and worry, physical injury, infection—and nerve stimuli of sufficient number or intensity inevitably cause exhaustion and may cause death. With rest, warmth, and sleep there is partial or complete cell repair; hence to avoid or minimize shock in operations the brain must be protected from harmful stimuli not only before and during, but also after operation. The authors

state that the complete exclusion of both traumatic and emotional stimuli will wholly prevent the shock of surgical operations. The ideal is practically unobtainable; but through a preoperative narcotic and an odorless, non-suffocating anesthetic, together with nerve blocking, gentle handling of tissues, and sharp dissection, the patient is protected to a very great degree.

After detailing their conception of the cause and pathology of surgical shock, the clinical phenomena of shock and its treatment, the authors discuss "anociation," by which term they mean the development of a technique which protects the patient from the various harmful stimuli. General technique is first described, then its application to operations in various regions and on various special organs. Since the authors and their associates have performed nearly 3,000 abdominal operations under anociation at the Lakeside Hospital and have noted a striking improvement in their results since that method was inaugurated, this book should be of the greatest interest to all surgeons.

REGIONAL ANAESTHESIA (Victor Pauchet's Technique).

By B. SHERWOOD-DUNN, M.D., Officier d'Académie; Surgeon (Colonel) Service de Santé Militaire de Paris; Physician to the Cochin Hospital. Philadelphia: F. A. Davis Company, 1920.

IN the preface the author calls attention to the difference between the infiltration anesthesia of Reclus, where the anesthetic is applied to the nerve endings in the operative field, and regional anesthesia, where the anesthetic is injected at the point of origin of the nerve or along the trunk near the point of origin, so that the whole region supplied by the nerve and its branches is anesthetized. He states that Pauchet is acknowledged to be the leading exponent of regional anesthesia in France, and this book constitutes a résumé of his writings upon this subject, together with those of Sourdat and Labouré. In addition there is included the latest experiences of Pauchet and the author, together with Pauchet's recommendations inserted during his revision and amplification of the manuscript just before publication.

The book is divided into seven chapters. The first, on general considerations, discusses the advantages and disadvantages of regional anesthesia; the second covers the armamentarium, the anesthetics and general technique; while the remaining chapters cover the special technique in connection with operations on the various regions and special organs of the body.

Regional anesthesia is applicable to 80 per cent. of surgical operations in the author's opinion; but it is usually combined with infiltration anesthesia and often, particularly in the case of beginners, must be supplemented by a slight to moderate amount of inhalation anesthesia, for which he generally uses ethyl chloride. The directions for nerve blocking in general and in special operations are clearly and concisely given and well illustrated by numerous diagrams, most of which are excellent. Some of the reproductions of photographs are, however, very poor. The author does not hesitate to point out what he considers unsuitable cases for regional anesthesia. Although the technique he much harder to acquire than one would suppose from reading some parts of this book, there is certainly a field for this type of anesthesia and Sherwood-Dunn has covered the subject conservatively and well.

DIE BEHANDLUNG SCHWACHLICHER KINDER IN OFFENTLICHER FÜRSORGE. Von Dr. JULIUS RITTER. Berlin: S. Karger, 1920.

THE author gives a series of interesting data concerning the necessity for rebuilding and strengthening the weakened children in middle Europe. The value of sunlight in destroying virulent bacteria is dwelt upon, likewise the necessity for sufficient perspiration to aid in the elimination of toxins through the skin. An interesting point given regarding anemic and chlorotic children is that despite the feeding of fat, carbohydrates, and proteins, the requirements of metabolism were not fulfilled until mineral salts were added to the dietary. His plea is for the addition of fruits and fresh vegetables to encourage growth. Gymnastics or massage, and the use of cold water for hardening the body are recommended. This little pamphlet is filled with such practical data that it affords very interesting reading.

Society Reports.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

One Hundred and Fifteenth Annual Meeting, Held in Brooklyn, May 3, 4, and 5, 1921.

SECTION ON SURGERY.

Tuesday, May 3—First Day.

Dr. LEDRA HEAZLIT, of AUBURN, IN THE CHAIR

Tumors of the Kidney.—Dr. THOMAS F. LAURIE of Syracuse made this presentation. He said that a very small percentage of these tumors were benign. Clinical manifestations and urological study showed that a great majority of these tumors were hypernephromata. The nature, source, and pathology were obscure. In malignant cases metastases were distributed through the blood stream. Early manifestations were not common and the growth was slow, so that if once a diagnostic clue could be obtained, early operation should be possible. The most common type, hypernephroma, was very malignant, and recurrence common. The older papers on this subject were based on clinical symptoms and signs, without resort to the exact diagnostic methods now in vogue, so that nowadays there should be better promise of cure in these cases. Three cardinal points of symptomatology should be noted: hematuria, tumor, pain. Hematuria was the most important symptom and occurred in 38 per cent. of the cases. It should be sufficient to attract the patient's attention in order to be noticed, but often was so profuse that it caused a clot formation in the ureter, with resulting renal colic. The speaker said that this symptom might last but a short time and recovery occur without the patient having noticed it. Later the surgeon would be confronted with an inoperable, malignant mass. In 42 per cent. of cases hematuria was the initial symptom. It was difficult to determine the difference between tumor of the kidney and that of other viscera; also tumors might be so small that they might not be palpable. When palpable it might be too late for surgical intervention. Pain occurred in 32 per cent. of the cases. The character and location of the pain might vary so much that it was often misleading. Other symptoms might be dilatation of the superficial blood vessels, caused by pressure from the growth, and perhaps toxins entering the vessels. The diagnosis of these lesions was very important, and if there were symptoms pointing to the urinary tract cystoscopy and x-ray examination should be carefully and fully carried out, the former, when the patient was still bleeding. The urine should be examined by microscope and by culture, and the bladder capacity and amount of residual urine tested. The kidney function should be determined by phtalein and urea and also careful search made for tubercle bacilli. A pyelogram should be made of the affected side, as a positive pyelogram was the most certain evidence of renal tumor. If the pelvis were involved the symptoms depended on the size and location of the tumor. The position of the pelvis might be changed, there might be changes in the drainage, and there might be slight evidences of early encroachment, palpable in early diagnosis. The only treatment was nephrectomy, provided there was enough kidney tissue on the other side to maintain the life of the patient, and when there were no metastases. Such removal could be supplemented by treatment by radium or the x-ray.

Tumors of the Bladder.—Dr. JAMES N. VANDER VEER of Albany presented this communication. He said that Kelly had enunciated three maxims relative to tumors of the bladder: "Extreme watchfulness is necessary at three stages: (1) cases must be brought for examination at the earliest possible moment in order to trace urinary hemorrhage; (2) they must be watched over a period of several months or longer; (3) they must be watched at first at intervals of several weeks, then several months, then for several years, to guard against recurrence." Very many urologists, the speaker said, were prone to neglect these maxims. Surgeons were apt to operate without due observation. Warner stated

that "Tumors of the bladder form 3 per cent. of all tumors and that 78 per cent. of them are in the male sex." Early disturbance of urination was often neglected, but the surgeon should be on the lookout then. Even urinary disturbance of a few days, such as burning, heaviness, interruption in evacuation, pain, pus, or sediment or microscopical blood should be noted; the latter often escaped the notice of the physician. No delay could be excused in these cases. Any condition beyond the meatus was a sealed book; the pages must be cut and the condition brought to light. One must have the necessary instruments, skill and resourcefulness in order to deal with these cases. Provided with the training and equipment the work should be successful. The cystoscopist should be the operating surgeon, or at least his right hand man. Some cases were impossible to cystoscope, (1) on account of severe pain; (2) because of malformations of the tract; (3) by reason of hemorrhage; (4) on account of the objections of the patient; (5) because no cystoscope was at hand; (6) through incompetence of the cystoscopist; (7) because of lack of instruments; (8) on account of previous operations. To make a proper examination, an anterior and a posterior plate should be made; a large sterile catheter should be passed and the bladder filled with air, till the patient complained of distention. Shadows of tumors should be properly interpreted. Radiography was easier than cystoscopy for many physicians. The speaker believed that opening the organ in cases of tumor gave more room for examination. Sometimes it was very difficult to determine whether a bladder growth was benign or malignant, and pathologists were often puzzled. Bryce stated they bled more easily when malignant, tended to necrosis and incrustation; they were meaty with thick pedicles; and cystitis was apt to be present. The pathology of the growth could be determined by frozen section in the laboratory and that would decide the amount of surgical intervention required. One worker had classified these tumors into three classes: (1) primary cytoplasia (disappearance of the first layer of cells; perhaps benign); (2) secondary cytoplasia with change of cells (precancerous); (3) metastasizing growths or tertiary cytoplasia (cancerous). **Operation:** No tumor should be operated upon except in a modern and fully equipped hospital. Intervention should now be accompanied with raying by the x-ray, or radium by the cross-firing method. In radium treatment of bladder should be washed frequently to remove bacteria, as the rays tended to destroy phagocytic cells. The Widal current could be applied through the cystoscope for the treatment of papillomata, and the operation could be combined with the partial snaring off of the tumor. If the tumor did not react well to this treatment the bladder must be opened and examined. The patient should be recalled frequently and watched. The rapidity of disappearance was in proportion to the degree of malignancy. Some operators made use of diathermy by the electric current. Radium therapy, while useful, had the disadvantage of being costly and not always available. Opinions differed very much as to the dosage but the consensus of opinion seemed to be that from 2 to 5 hundred mg., screened with a 2 mm. lead or silver screen for 12 hours was safe. The substance acted in inverse proportion to the square of distance from the tissues. It would be well at the present time to harmonize the difference in methods and fix on a definite milligram dosage for a certain number of hours and compare results by this method.

Dr. Cross of Buffalo said that early diagnosis was of the greatest importance. In bladder tumors hematuria was the initial symptom and always pathological. Bladder tumors were apt to metastasize slowly due to the small number of lymphocytes. He recalled one patient who was operated on in 1907, 1911, and 1914, and was seen in 1919 with the bladder full of papillomatous masses. The man was given radium treatment, but the growth recurred within four months. The fulgurization method gave better results and he was free one year from disease, then there was a small recurrence, which yielded to fulgurization. Fourteen years ago the process was reported as malignant at the first operation. Those tumors that did not respond to fulgurization were probably malignant. The difference

between clinical and pathological findings was frequently noticeable. One type clinically benign was reported by the pathologist as malignant. Other tumors reported benign, and looking benign, later turned out to be malignant. It was best to take a portion near the base of the tumor, and the pathologist was less likely to make a mistake by this means. A new form of treatment was by the injection of millicurie seeds into the tumor through a hollow needle. These were allowed to remain, being so small that they passed off, without the danger of starting the nucleus for a stone. Dr. Vander Veer had mentioned the difficulty of cystoscopy. The minimal amount of discomfort could be obtained by opening a tight meatus, and then, by anesthetization of the posterior urethra with a half ounce of 1 per cent. solution of cocaine reaching the trigon, and later a half ounce of a half per cent. cocaine solution, freedom from discomfort could be obtained.

Dr. A. VANDER VEER of Albany said that in regard to Dr. Laurie's paper, one patient was under observation for pain in the right side of the abdomen which was thought to be gall-bladder condition. There were no kidney symptoms. He had made a mistake in the diagnosis, because somebody did a nephrectomy later at Johns Hopkins, although the patient had nothing to indicate that the trouble was renal. The urine was negative. Pyelograms were made and the report stated that there was a perfect pelvis. The patient later said that the surgeon at operation found a hypernephroma the size of a hickory nut at the upper pole. Another case was recalled which the speaker said amounted to medical malpractice in which the patient was allowed to go three months with a large mass as big as a baby's head, in the left side of the abdomen; the physician who saw it said that it was a big kidney and that the patient probably had only one kidney. Then there was a profuse hemorrhage and the patient, suffering intense pain, came to see the speaker. A nephrectomy was done and the patient was free from pain one year and a half; then he died suddenly. This was the type of case usually considered inoperable, so that it showed that in some of these cases some good could be accomplished by operation. That man was a salesman and he was able to work for more than a year. In other cases with negative diagnosis and pain in the lumbar region, one should operate, for there was a small type of hypernephroma involving the capsule, and not invading the pelvis, which did not cause hemorrhage, and which called for operation.

Dr. ABRAHAM HYMAN of New York said that last year a series of 40 tumors of the kidney were reported on Dr. Beer's service at Mt. Sinai. There were 28 hypernephromas. A few points of interest should be brought out. Cases were examined too little. The laity, and physicians also, were not alive to the seriousness of hematuria. The Public Health Service issued a pamphlet dealing with early symptoms of carcinoma of the cervix and of the breast, but it was surprising that such an important symptom as hematuria was not mentioned. Many physicians took the same attitude. The doctor was apt to tell the patient that the hematuria did not amount to much because it stopped spontaneously. Of the 28 hypernephromas some were treated for nephritic hematuria. In some cases no known factor could be found. One man had several attacks of bleeding and a large number of hyalin and granular casts, blood casts. The function of both kidneys was identical and x-ray negative. By forcible manipulation of the catheter in the renal pelvis a profuse hematuria was produced on the affected side, and this gave the clue. The pyelogram showed merely some irregularity in the pelvis. At operation a large hypernephroma was found which had broken into the pelvis. Three or four cases had been detected by this sign alone. A bimanual rectal examination, with one finger in the rectum and the other on the abdomen, was useful to make a diagnosis of malignancy. Twenty-five per cent. of tumors were probably malignant. The high frequency current could be used in some cases, but not in fleshy growths or multiple papillomata. Dr. Beer had elaborated an operative technique directed to avoid implants of tumor on opening the bladder.

Dr. THOMAS F. LAURIE of Albany, in closing, said that in recalling Dr. Vander Veer's early cases, he

thought that after all methods of examination had been used, exploratory operation was justifiable. If the tumor did not invade the pelvis, the pyelogram would be worthless. He could not say whether Dr. Hyman's manipulation of the catheter was diagnostic or not. He thought that in the normal kidney or ureter, a forcible manipulation might well provoke bleeding. If bleeding were found on both sides it would prove nothing. In regard to the fulguration method, recurrences were seen sometimes. He had one man, a Russian, operated on at 14 years of age for single papilloma. At 28 years he had a recurrence and radium was suggested, but the patient thought fulguration had given good result before, and decided to keep on with it. These patients should not be allowed to drift. Where radium could be used it should be. He had one patient alive after five years, with one-third of the bladder removed. Somebody would probably say "Why don't we snip off portions of the papilloma and send it to the pathologist?" That reminded him of what Dr. Pick used to say in Berlin, when Israel sent him specimens. He said that "Israel sent him the top of the house, and expected him to know what was in the cellar."

Surgical Aspects of Disease of the Gall-Bladder and Biliary Passages.—Dr. ABRAHAM O. WILENSKY of New York City presented this paper. He stated that cholecystitis and cholelithiasis were diseases of middle age, more common in women, especially in multiparae. Probably the disease began early in life and showed symptoms later. In one type gallstones occurred, in another not. In the first, at operation various pictures were seen: (a) Normal gall-bladder, with light bile and varying number of stones; (b) slightly dilated bladder with single stone; (c) large distended bladder, atrophic mucous membrane, numerous stones; (d) neglected gall-bladder, thickened, gangrenous mucous membrane, numerous stones, cystic duct often shut off; (e) gall-bladder shrunken, varying amount of pericholecystitis, cystic duct sometimes obliterated; (f) gall-bladders corresponding to a, b, and c, and (g) corresponding to e and f with stones, (h) corresponding to f, without stones. Infection might begin in two ways, (1) acute catarrhal cholecystitis, or empyema of the gall-bladder, (2) disturbance of cholesterolin function, often beginning in pregnancy, corresponding to the hypercholesterinemia of pregnancy. The stones would act as foreign bodies and the infection accompanied disturbed metabolism. The complicating factors caused pathological pictures of wide variation. Once infection sets in mechanical means must be taken to remove it. Anatomical healing only increased the deformity. Often the liver itself was affected; and there was leucocytic infiltration of the portal sheaths. The liver had an appearance of early cirrhosis, suggesting the idea that continued diseased foci could start cirrhosis. Pancreatitis set up as a response to bacterial infection. Other important lesions could rise from neglected gall bladder disease. There was no method or process, at present, by which gall-bladder disease could be ascertained at an early date. The history gave the most important data. The clinical types were varied: (1) One or more attacks separated by healthy periods; (2) attacks accompanied by pain and ill health; (3) dyspepsia and gastric symptoms; (4) right-sided abdominal pain, suggestive of dislocated kidney, or chronic appendicitis (the presence or absence of biliary colic should be diagnostic); (5) single acute inflammatory condition with pain in the upper right quadrant, with nausea and vomiting, with tenderness near the gall-bladder (the acute empyema cases, not necessarily associated with stones). The treatment in gall-bladder cases should be surgical. Medical treatment was simply palliative, and operation should be done as soon as the diagnosis was established. The question of cholecystectomy versus cholecystotomy should be discussed. The former should be done whenever possible, and the latter only when nephritis, or myocarditis, or some similar complication precluded the added risk. Drainage was simply a palliative measure. In cases where there was disturbance of cholesterolin metabolism, bile drainage relieved the excess of cholesterolin in the body, as in pernicious vomiting of pregnancy. In some cholelithiasis cases it was difficult to determine whether the stones accounted for the symptoms and whether some reurred or were overlooked. Deaver advised opening

wide the common duct and draining to avoid overlooking small stones.

Cholecystitis.—Dr. MARSHALL CLINTON of Buffalo read this paper. He said that there was a disparity of numbers in the cases of gall-bladder diseases occurring in the sexes; four-fifths of the cases were in women, and 80 per cent. of these had borne children. It was found that regurgitation of trypsin through the sphincter of the ampulla produced nausea and vomiting, and work had been done to see if there was any relation between this fact and cholecystitis. A high percentage of women who had suffered from morning sickness were found among the gall-bladder patients, and any condition that produced nausea and vomiting had the primary symptom that produced gall-bladder disease. The speaker emphasized this relation to the regurgitation of trypsin in view of the fact that Rosenow had recently decided that gall-bladder infection arose from infection of the teeth and tonsils, and at the Mayo Clinic 10,000 children had had their tonsils removed to see what effect this would have on hematogenous infections in the future. He asked whether the profession was not too hasty in removing tonsils, and whether the victims received relief commensurate with the expense and trouble to which they had been subjected.

Dr. Cross of Buffalo said that it was now known that cholecystitis and cholelithiasis were largely due to bacteria. This was sometimes favored by congestion of the liver, such as occurred during the period of pregnancy. Rosenow had shown that there existed a selective action of certain bacteria. Deaver for many years had claimed that there was a certain interrelation between appendicitis and gall-bladder disease. Early cases produced few symptoms, but later lesions became more complex, depending upon the amount of infection. Gall-bladder infections became systemic, and were sometimes associated with pancreatic involvement. In some cases the lesions produced few symptoms, but in others there were marked systemic disturbances, anemia, and even hemorrhagic conditions. The early history was of disturbance in the epigastrium, and this increased as infection and movements of the stones took place. Lyons' treatment by magnesium sulphate was of use occasionally, but in cases of obstruction of the common duct it was useless and waste of time for the patient. Cholecystectomy was safer and quicker than cholecystotomy. Another point was careful manipulation of the tissue in that region. The common duct should not be ligated and abnormalities of the cystic duct and arteries should be recognized. In one case the hepatic duct was one continuation of the common duct. Certain bacteria from the appendix would produce cholecystitis, but it could be produced by other bacteria. With early operation the mortality could be reduced to 2 per cent. and less damage would be rendered to other organs. A long incision, and good anesthesia was necessary. Any drain was better than no drain. Two quarts of saline on the operating table would make the patient more comfortable. Lavage of the stomach tended to lessen nausea and vomiting, and prevented distention.

Dr. A. O. WHIPPLE of New York City said that in analyzing a large number of cases one was struck with three types: (1) fulminating streptococcal cases; (2) peritoneal infection through the portal route, as in pernicious vomiting; (3) infection through the circulation, usually by *B. coli* invasion. Ehret found this organism in the duodenum; Stokes isolated it in the common duct.

Dr. W. D. JOHNSON of Batavia said Dr. Wilensky had struck the essential point when he said that 75 per cent. of cases occurred in women and 80 per cent. of these in multiparae. He had read a paper on the toxic vomiting of pregnancy, in this society, in the obstetrical section, and had advised draining the gall bladder. This cured the condition in 48 hours.

Dr. SANLIER of Poughkeepsie said that one operative complication should be mentioned; that in cases of neglected gall-bladder disease there could be an excessive drainage through the common duct, producing dehydration, amounting to as much as 12 pints of fluid per day for three days, which could become very serious to the patient. An extensive study of the literature had not revealed any similar cases reported. A year ago a Philadelphia surgeon reported a case but neither

could he find the matter mentioned in the literature. Dr. AARON of Buffalo said he had reported an anastomosis between the duodenum and hepatic duct in a case of complete obstruction of the common duct, where bile had been suppressed entirely for three months. The patient had had nine operations already, and refused to have another, for which one could not blame him. As a last resort magnesium sulphate, dry, on the tongue, was tried, with enough water to wash it down. After four days bile began to flow and the patient was relieved. Probably congestion was lessened.

Dr. EDWIN BEER of New York City said that in regard to the remarks of the previous speaker, the physiological action just described could be attributed to magnesium sulphate. He had had the same experience in common duct surgery as Dr. Sadlier had, and had seen an enormous flow of clear bile which he took to be pancreatic secretion. Why women should have so much more trouble with gallstones than men was easily understood, in view of the fact that cholesterinemia existed in pregnancy. There was a strict analogy between uricemia and uric acid stones in the urinary tract, and cholesterin stones in the biliary tract. To those who worked in both fields it was striking how often patients with prostatic obstructions showed uric acid retention. Females showed cholesterin retention, due to hypersaturation of the blood. Uratic stones formed in one case, cholesterin calculi in the other. In prostatic cases bladder stones were uratic in 50 per cent. How and why they formed was to be solved by careful analysis of colloidal chemistry. The salts were in supersaturate solution and were thrown out when the colloid-holding material was reversed. Inadequate drainage of the common duct was wrong; there were good reasons for draining it for a considerable time. Secondary drainage had been overlooked and intra-hepatic stones could pass through the drainage tube.

Dr. HYMAN of New York said that formerly men were worried about removing tonsils, and now they were worrying about the appendix. Opening the pancreatic duct with the common duct was more apt to give involvement of the pancreas. Dr. Beer had pointed out that there was an analogy to formation of kidney stones. Did the pressure from the pregnant uterus cause stagnation in the common duct and gall bladder?

Dr. A. O. WILENSKY, in closing, said he had seen drainage of duodenal juice through the common duct from a fistula, with one stone coming from a paralyzed sphincter; the sphincter being incompetent the duodenal juice leaked. This was due to traumatism during operation with secondary necrosis. Cholesterin was increased, during, and several months after pregnancy, and patients had symptoms more from hypercholesterinemia than from stones. Proper diet would relieve symptoms. Patients would come back with symptoms after operation, but these could be controlled by simple attention to diet.

Dr. MARSHALL CLINTON, in closing, said that in one case of pernicious vomiting of pregnancy, where the patient could not even retain water, he decided that draining the gall bladder should prove the facts. The gall bladder was found filled with tarry bile, no stones, and there was a great deal of trypsin. Forty-eight hours after drainage vomiting stopped. The fourth day she had slight depression. The next day she was delivered of a five months' dead fetus. The sixth day she died, but it was certain that drainage stopped the vomiting. In other patients it had been observed that trypsin was never found except in those with nausea. The trypsin might be pushed back from the pancreas.

SECTION ON MEDICINE.

Tuesday, May 3—First Day.

*Joint Meeting with the Section on Public Health,
Hygiene, and Sanitation.*

DR. NELSON G. RUSSELL OF BUFFALO IN THE CHAIR.

The Relation of the State Department of Health to the Medical Profession.—Dr. MATTHIAS NICOLL, Jr., presented this communication, in which he stated that in discussing the history, growth, and present status of
